CANADIAN MACHINERY

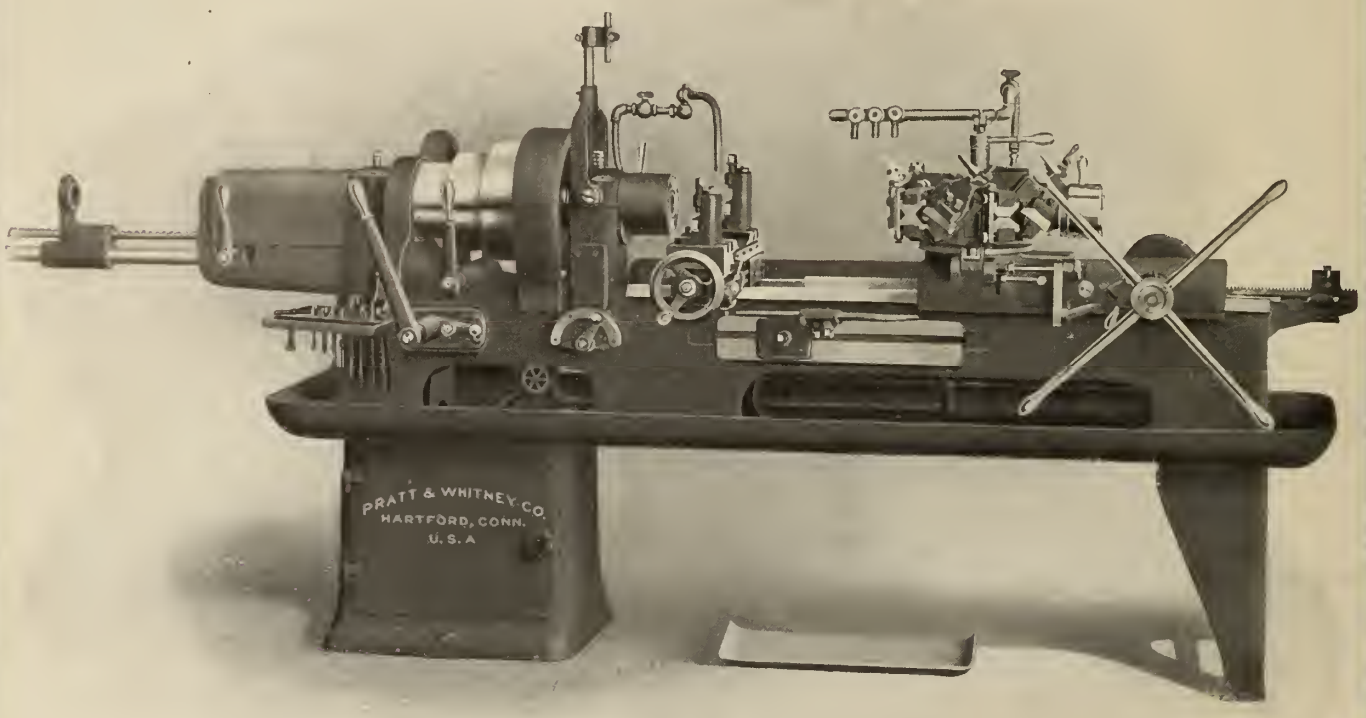
AND MANUFACTURING NEWS

JANUARY
1906

TURRET LATHES

BUILT IN FIVE SIZES:

$\frac{5}{8}$ x $4\frac{1}{2}$, 1 x 10, $1\frac{1}{2}$ x 18, 2 x 26, 3 x 36.



2 x 26 inch Turret Lathe for rod work up to 2 inches diameter and 26 inches long

ON BAR WORK FROM $\frac{1}{2}$ to 2 INCHES DIAMETER THIS MACHINE WILL DO THE WORK OF FROM 3 to 6 ENGINE LATHES. The double cross-slide which is used on all sizes of these machines enables forming and cutting off to be done at the same time the turret tools are at work. The turret stops, one for each tool in the turret, are easy to adjust and simple in construction. These machines may also be used to advantage on chucking work.

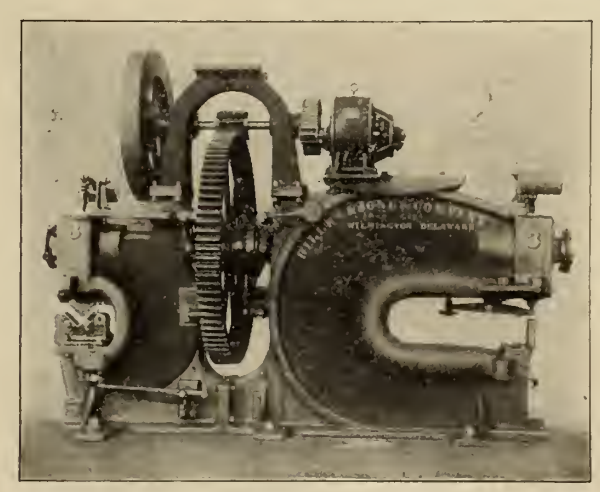
WE MAKE Wheelock Engines, Corliss Engines, Ideal High Speed Engines, Boilers, Pumps, Flour Mill Machinery, Oatmeal Mill Machinery, Wolf Gyrators, Emery Choppers, Woodworking Machinery, Shingle Machinery, Heading and Stave Machinery, Wood Rim Split Pulleys, Iron Pulleys, Shafting, Hangers, Friction Clutch Couplings, Friction Clutch Pulleys, Safes, Vaults, Vault Doors.

Westinghouse Motors

Increase Production—Decrease Costs

Individually driven tools can be used independently of the rest of the shop equipment, and require only the power necessary to operate the driving motor.



Individually driven tools solve all the various problems of the shop lay-out; they can be placed where most convenient to the work required.

"CINCINNATI" HEAVY DUTY SHAPERS

Are built to stand the excessive strains caused by heavy cuts and big feeds with high-speed steels. All sliding bearings have taper gibs, adjustable endwise by single screws, and the crank block is drop forged. A high-gear ratio, an ample amount of cast-iron properly distributed, and high-class workmanship, combine to place the "CINCINNATI" in the front rank. Catalog on request.

Merrell Motor and Engine Driven Machines

Motor Drive

These machines have our standard adjustable quick-opening and closing die heads and our improved cutting-off knife. The chasers are five in number for No. 5½ and No. 6½ machines, and six in number for No. 9½ machine, and eight in number for No. 11½ machine. They are set by graduation to any size desired, are released from threading while in motion and opened to permit of pipe being cut off and closed instantly and positively. These machines will do far more rapid work, both in threading and cutting off, than any other combined machine on the market.

Write for Catalogue.

MONTREAL, TORONTO, WINNIPEG, VANCOUVER

HOW MUCH OF YOUR POWER IS WASTED?

During 1895-96 a series of experiments were conducted by Prof. C. H. Benjamin, of Cleveland, Ohio, to determine the ratio of the power required to drive shafting and belts, to the total power consumed, in 12 manufacturing plants on both light and heavy work. The results were as follows:

TABLES

Manufacturing Plant Number	Total Horse-Power	Horse-Power to Drive Shafting	Per Cent. to Drive Shafting	Manufacturing Plant Number	Total Horse-Power	Horse-Power to Drive Shafting	Per Cent. to Drive Shafting
1	400	157	39.2	7	40.4	20.7	51.2
2	74	57	77	8	74.3	40	53.8
3	38.6	25.3	65.6	9	47.2	24.5	51.8
4	59.2	47.9	80.7	10	190	108	56.9
5	112	64	57	11	107	74.5	69.7
6	168	91	54.2	12	241	114	47.3
Average, heavy machine work	....	.....	62.3	Average, light machine work	.....	.....	55.1

75 per cent. saving is what we guarantee on shaft friction.

Over 200 of the leading Canadian factories are equipped with Chapman Double Ball Bearings.

WHAT POWER DO YOU USE?

We don't know, but we know what you should use.

GAS OR GASOLINE, DISTILLATE, KEROSENE OR CRUDE OIL

Why?

Because these are **the** powers of to-day.

Figure it out.

If you have a steam plant you have to keep fire going nearly all the time.

You need one or more men constantly in charge. Your coal keeps on burning whether the engine is running or not.

We could mention more, but won't now.

Take a Fairbanks-Morse Gas or Gasoline Engine.

When you are ready for power you start it, and it only takes a moment.

You can shut it down just as quickly.

Fuel consumed is only in proportion to the load on the engine.

It requires no attention after being started, until you want to shut it down.

Did you ever take the trouble to enquire into the merits of this form of power, and see how totally different Fairbanks-Morse Gas and Gasoline engines are from other makes?

Modern Canadian Manufacturing Plants.

ARTICLE XI.—The Canada Car Company, Limited, Montreal.

ONE of the newest and most up-to-date of large Canadian manufacturing plants is that of the Canada Car Co., Limited, at Montreal. The first sod in the construction of the plant was turned in October, 1904, while on October 14 last the production of cars first began, thus coming close to forming a record for rapid construction in Canada. Some of the details of construction of this plant were given in a former issue. Owing to the vast amount of detail work necessary to produce perfect results, the shops have by no means reached their full capacity, which will be about twenty-five cars a day. However, the daily output has been steadily increased, and has now reached the respectable total of eight freight cars a day, while, on account of the non-arrival of material, work has not advanced very far in the passenger car department.

View from Upper Lachine Road—Canada Car Company's Plant.

The ideal situation of the works, with the Lachine Canal to the south, and the Grand Trunk main line immediately to the north, will at once appeal to the visitor as affording the best possible facility for the arrival of raw material and the delivery of the finished car.

At the west end of the plant is situated the lumber yard, a system of overhead carriers bringing the lumber from the canal to the yard and thence, when desired, to the planing mill. A spacious dry kiln is convenient to the lumber yard, and in the vicinity, too, is situated the stores department, where a fine system is in operation, practically all the metal used in constructing cars being here under cover.

The Planing Mill.

Entering the works at the west end, we come first to the planing mill, a room 365 feet long by 70 feet wide, where the first machine encountered is a band rip-saw, which is used when necessary before the planer. Two large No. 41 Berlin timber planers take care of the sills and all heavy timbers going into the cars, dressing them on four sides simultaneously. Each of these planers is driven by a 75 h.p. motor. The lumber next goes to a cut-off saw, where it is cut to proper lengths and marked off, after which it is taken to the tenoning machine installed by Greenlee Bros. & Co. The boring machines, horizontal tenoner and hollow chisels in succession, are put to work on the timber, which is then ready for the erection shop. Smaller timbers, such as belt rails, after going through a 16 x 5-inch planer, and the cutting saws, are marked off for boring and hollow chiselling, after which operations they are put in readiness for the erection shop by the tenoners. With the exception of one small group, every separate machine in the planing mill has its own motor, and is perfectly independent of every other machine. These are three-phase, 60 cycle, 550 volt induction motors of Canadian Westinghouse make.

Adjacent to the planing room is the department given up to turning out tongued and grooved flooring, siding and roofing for box cars. The dimensions of this department are 215 feet by 70 feet. A band rip saw, three 6 in. by 15 in. lightning floorers, or planers and matchers, and three automatic cut-off saws, constitute the main mechanical features of this department, but there are also several miscellaneous machines, such as molders and surfacers.

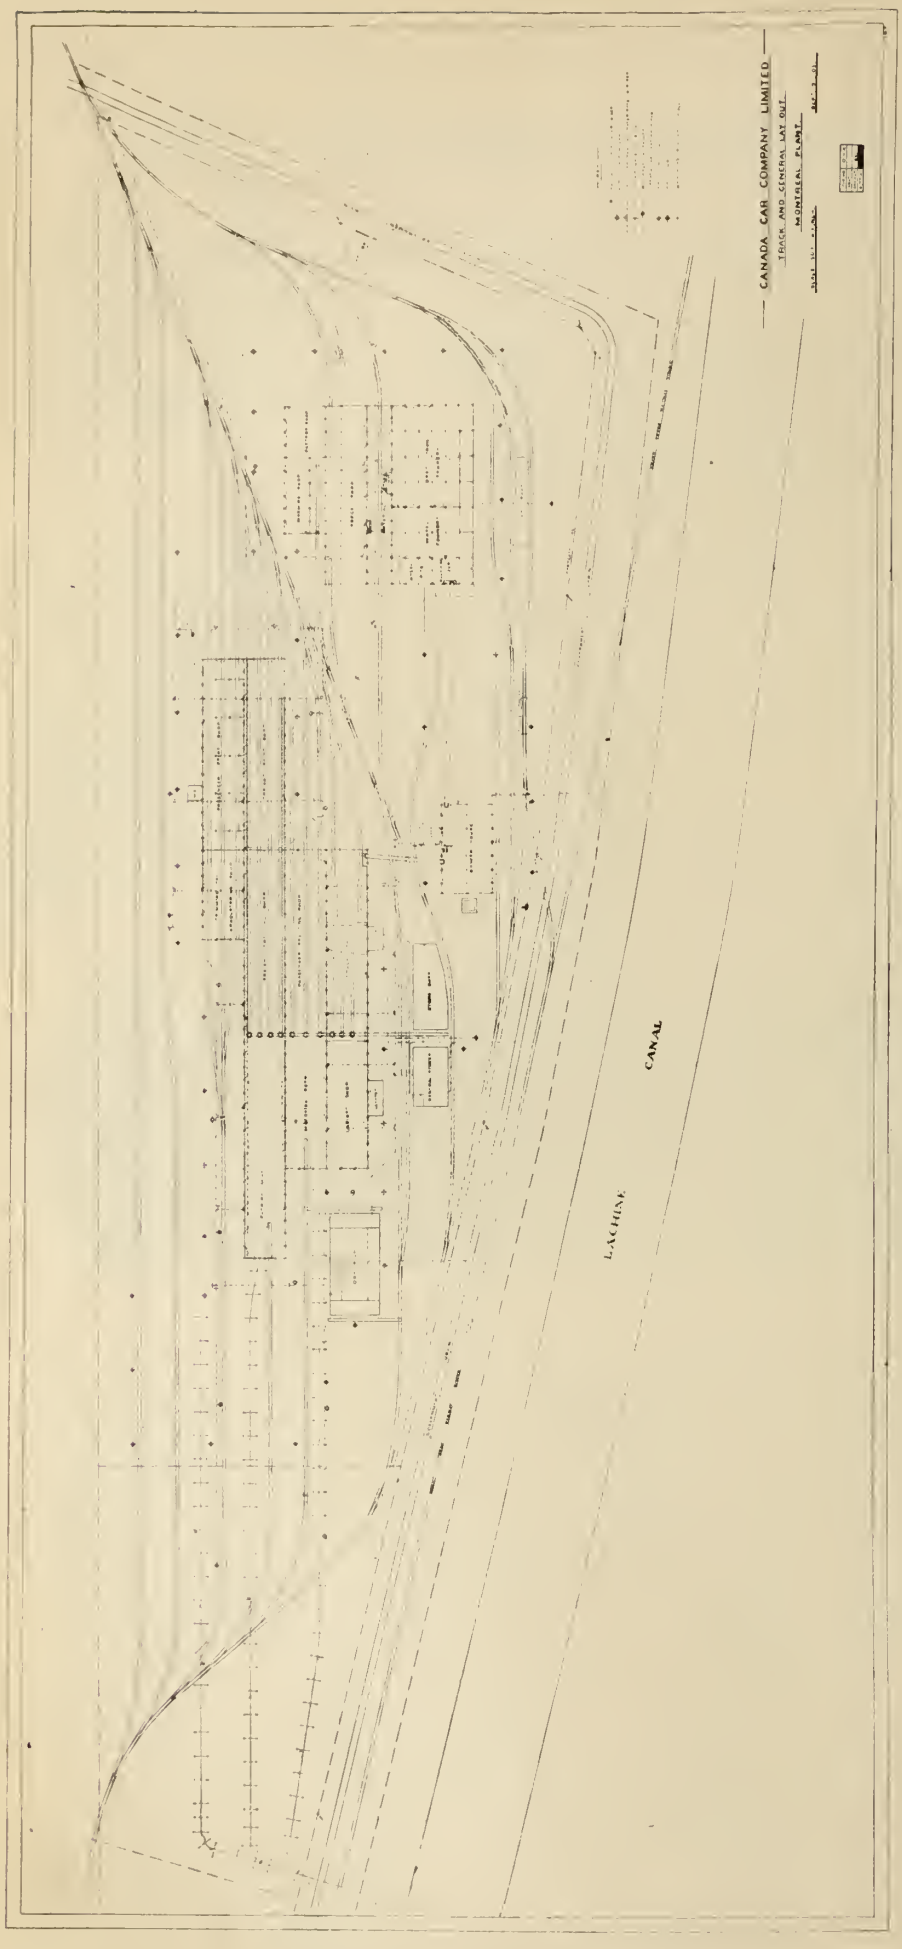
The rough material for flooring, siding and roofing, is brought in and put through the planing and matching machines to surface it, and make the tongue and groove. It is then passed on to cut-off saws, which cut the boards to proper lengths, when they are ready for the erection shop, or door department, as is necessary.

Erection of the Cars.

After the material has passed through the planing and matching rooms, the next step is the assembling, which is done in the erection shop. The trucks come to this shop more or less complete, and the body bolsters are put into position to receive the sills. Piece by piece the various parts are put together, until the car is finished, when it is pushed out into the next department, which is the paint shop.

The Paint Shop.

In this shop the cars are given the required amount of paint, which is sprayed on by air pressure. The air piping and general air brake equipment



Canada Car Company, Limited, Montreal—Track and General Lay Out.

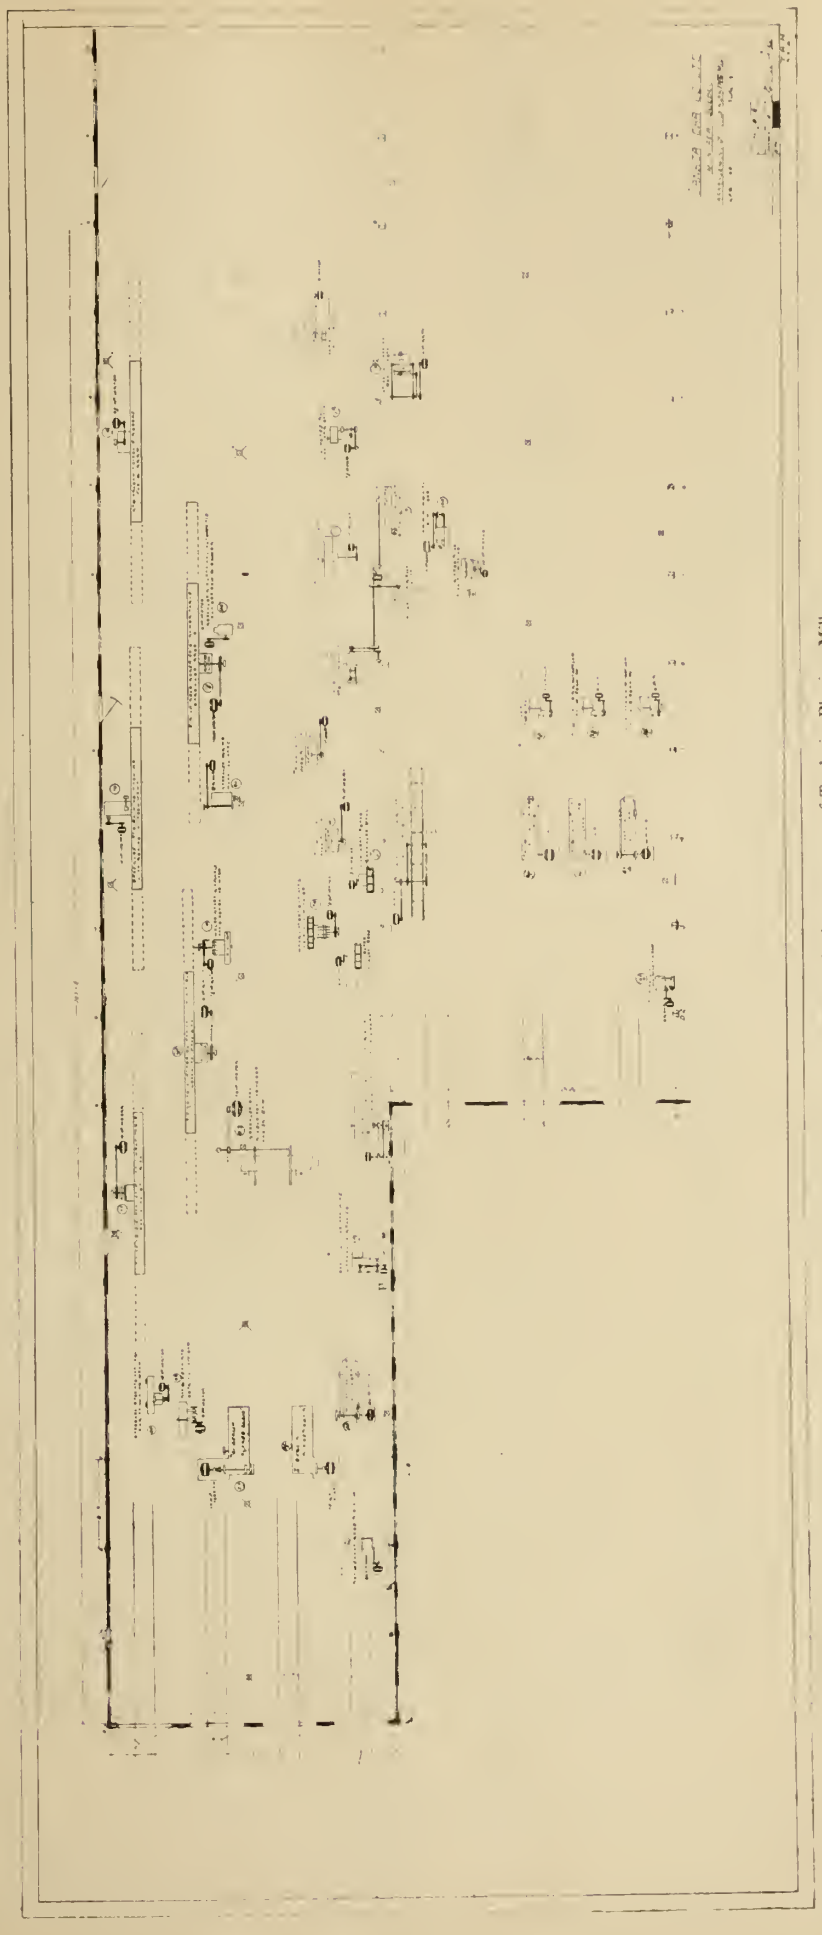
is also applied in this room, and the cars are then tested and weighed, preparatory to being delivered to the various railroads and put into service. All these departments are under one roof.

We have now traced the progress of the lumber, from the time it enters the lumber yard by overhead travelers until the freight car leaves the paint shop ready for delivery. But it is really of greater interest to note the various processes undergone by the metal parts of the car in another building containing the different departments for these operations.

The foundry is said to be the most modern in Canada, and has been equipped throughout by the Whiting Foundry Equipment Co., of Chicago. To the south of the foundry is kept the supply of such material as coke, pig iron, scrap iron and steel. A pneumatic trip hammer is here employed to break up old wheels, while a Fairbanks scale, convenient to the breaker, permits the workmen to load transfer cars with the correct proportion of pig iron, scrap and steel. They are then run into the foundry room and raised to the charging floor on a pneumatic hoist. The grey iron and wheel foundries are connected, but there is a separate hoist for each foundry, so that, if one goes out of order, the other can do double duty. The charging room is the best in the country, with capacity to store a week's material if necessary. This is an important consideration in a climate such as ours.

When the transfer cars have been hoisted to the charging floor, they are run along the tracks to the cupolas, of which there are four, two for the grey iron and two for the wheel foundry, with capacities ranging from 10 to 20 tons. A charging device, the first of its kind in this country, has been installed here. The truck bearing the charge comes to a stop on a platform, which, by the agency of compressed air, is tilted up so as to dump the charge into the cupola, thus saving a great deal of time. On a sub-floor are situated two Roots' Blowers, No. 7 and No. 6, supplying blast for the wheel and grey iron foundry, respectively. Both are connected with the main blower line and either can be used if the other breaks down.

In the foundry proper one is greatly impressed with the fine track system for delivering iron. The tracks and turntables are so arranged that the molten metal can be delivered to all parts of the shop. A feature of the grey iron foundry is the Whiting patent roller drive tumbler for cleaning the castings. From the machine the castings are taken to the door, weighed and



Canada Car Company, Limited, Montreal—Arrangement of Tools in Planing Mill.

put on cars to be transferred to the erecting shop.

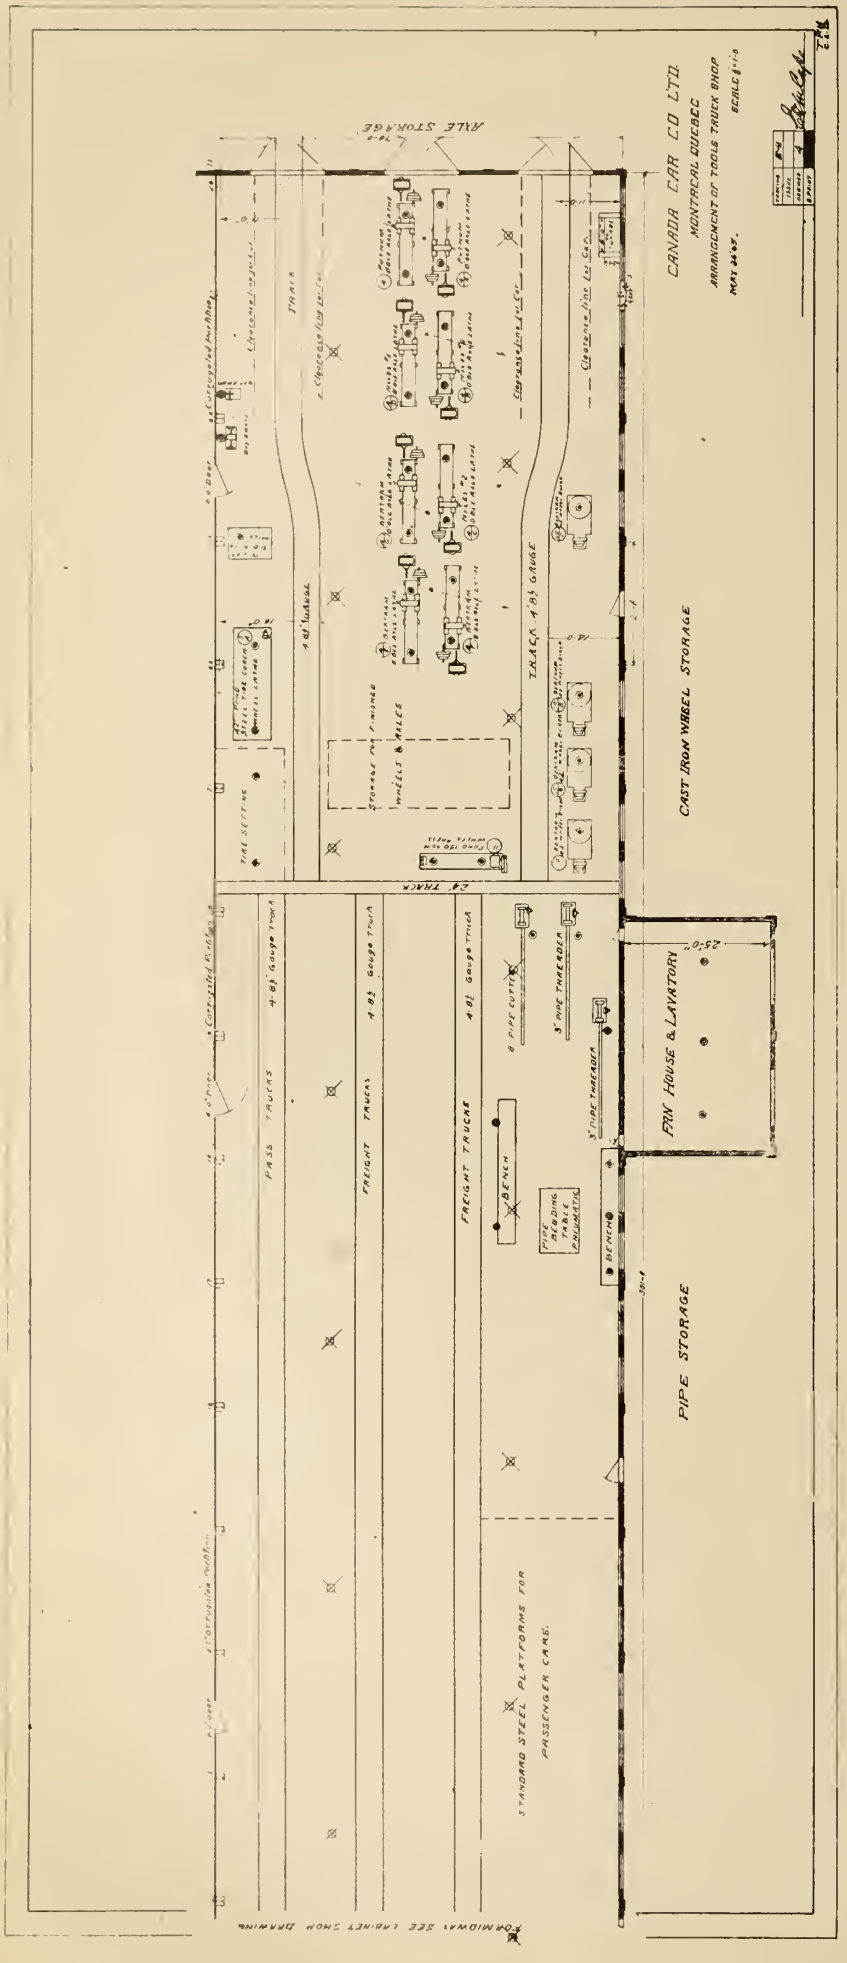
In the wheel foundry are cast the car wheels, the system of tracks and overhead carriers making it able to turn out the wheels with clock-like regularity. The whole foundry is arranged for a daily output of three hundred wheels. After the wheels have solidified in the molds, they are carried down to the transfer cars, and then taken to the annealing pits. These pits, numbering 96 in all, are 12 feet deep and lined with 4½ inches of firebrick, and have an individual capacity of 18 wheels. This allows for a daily production of 300 wheels, giving sufficient time to anneal. A Whiting pitting crane of 3,000 lbs. capacity, equipped with a double hoisting device, works the full ten hours of the day, taking out the wheels in the morning and depositing them in the afternoon. The core ovens, which are equipped with rolling doors, are also arranged to contain 300 pan cores and 300 centre cores. They are very compact, and no space in them is unused. There is in connection with the plant a splendidly equipped pattern shop with the machines necessary to turn out patterns for the grey iron and wheel foundries.

Forge and Smith Shop.

One of the most interesting departments in the plant is the forge and smith shop, where all the wrought iron work is done for the cars. The iron storage is at the east end of the shop. From here the material is brought in and sheared to proper lengths, being then marked off and forwarded to various machines to be upset, shaped, punched or drilled, or put through any of the necessary operations to finish it properly for delivery to the erecting shop. Among the heavier machines in this shop are an Acme Machine Co.'s 4-in. upsetting machine, an Acme 3-in. upsetter, a Williams & White bulldozer No. 8, and some smaller sized bulldozers, a Bement-Niles 2,000 lb. double legged steam hammer, and numerous other machines of larger or smaller capacity, for the various operations that are required for the blacksmith department of a car shop. All the furnaces in the smith shop are oil burning, with an air blast of about 10 ounces.

Machine Shop.

In connection with the forge and smith shop, there is also a machine shop, which takes care of the making of the dies, and any necessary repair work for the plant equipment. Among the machinery features here are a large planer and lathes from John Bertram & Sons, Limited, Dundas, and a Brown & Sharpe milling machine.



Canada Car Company, Limited, Montreal—Arrangement of Tools in Truck Shop.

The Truck Shop.

A very important part of the work is performed in the truck shop. Here the axles (made of best forged steel) are turned out and the wheels are bored to prepare for the 150-ton hydraulic wheel press which presses the wheels on the axles. They are then delivered to the erecting floor, where the trucks are assembled. For turning the axles the most improved of double-headed axle lathes of three different makes are employed. These are the Putnam, Niles and John Bertram & Sons' lathes. For the boring of wheels there are 4 Bertram 48-in. wheel borers.

From the wheel press the wheels are taken to the erecting floor, where are also delivered the arch bars, truck bolster materials, castings, and other pieces of iron work, which come from the foundry and forge shop. These pieces of material are then assembled and the completed truck is ready to go to the erecting shop, where the freight cars are built.

Passenger Car Construction.

We have thus described the process undergone in the erection of freight cars. The process of manufacturing passenger cars is very similar, though the work is of a finer grade.

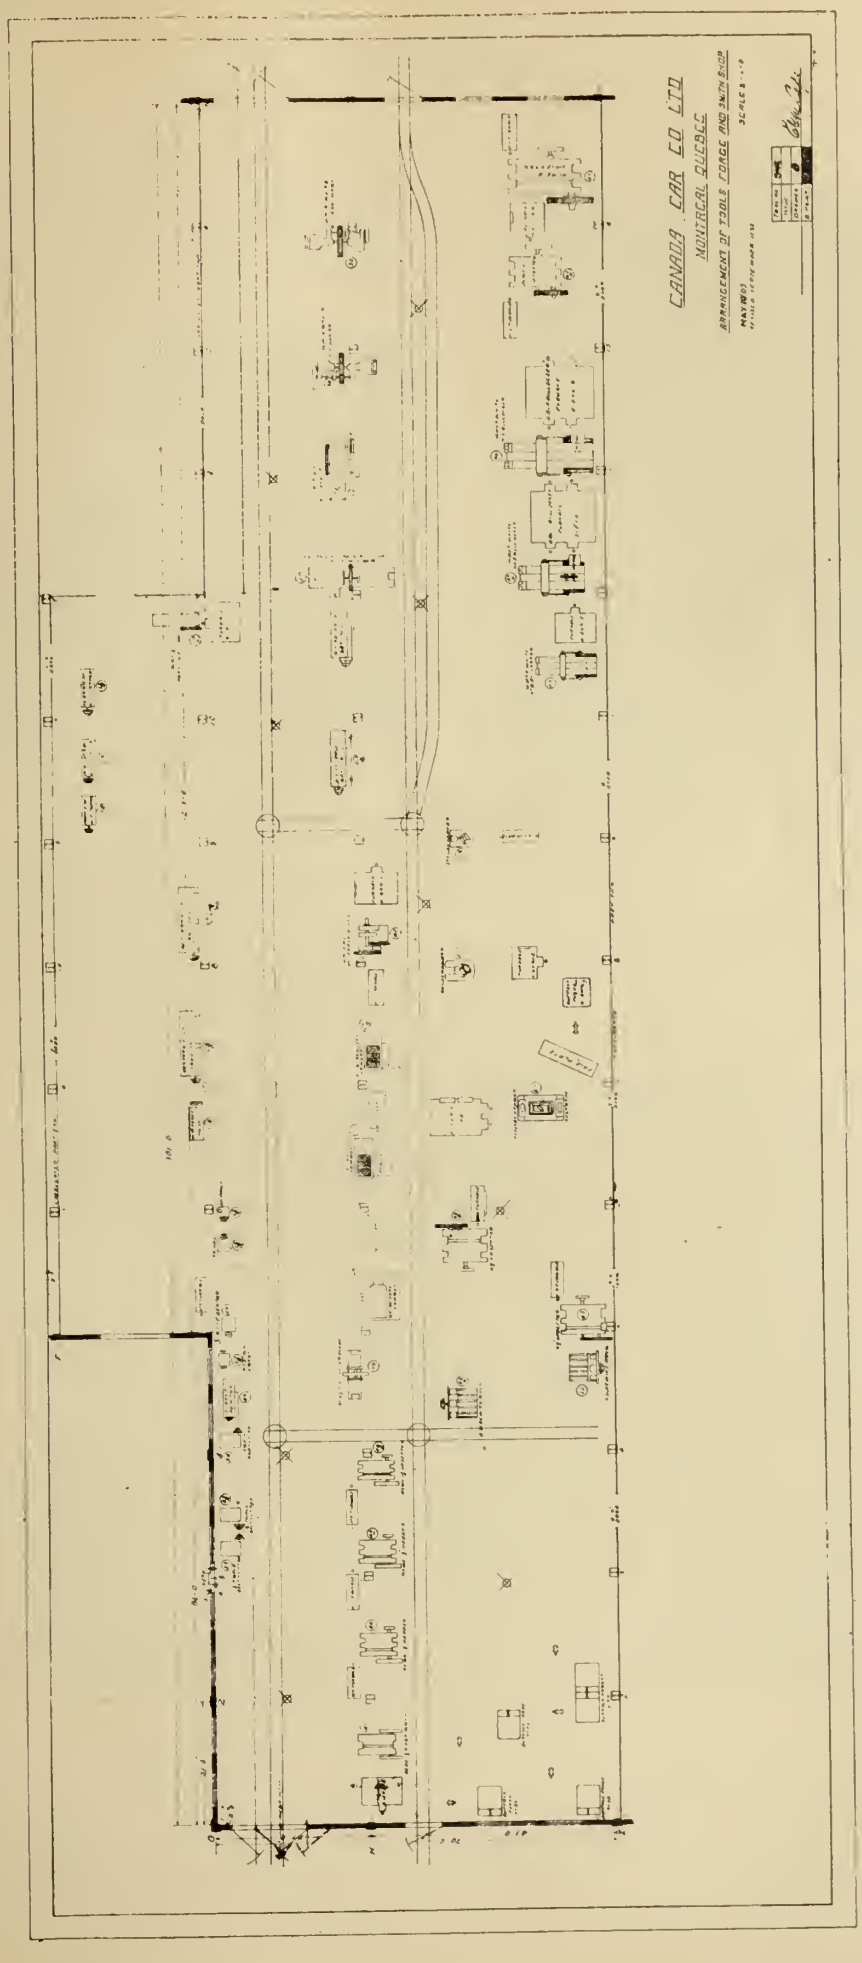
The planing and matching rooms will take care of the sills and rougher material, and deliver it to the passenger erection shop, which is adjacent to the freight erection shop. The wheels and axles will be finished in the truck shop, and transferred to the truck erecting department with the iron work from the forge shop. There is one track on the erecting floor of the truck department which has been reserved for the building of passenger trucks. After they are assembled they will be delivered to the passenger car erecting shop.

To produce all the inside finish and the finer grade of wood work that goes to make up the modern passenger coach there is a cabinet shop supplied with machines adapted for turning out this kind of wood work.

After the passenger cars have been erected, that is, after the wood work is completed, and the framing and most of the inside finish in place, the cars will be taken to the passenger car paint shop, where they will be given their different coats of paint and varnish. They will then go on to the upholstering department, where they will be completed and made ready for delivery to the railroad.

Traveling Cranes.

In the matter of traveling cranes, such as are absolutely necessary in a shop requiring so much heavy lifting as this plant, the Canada Car Co. is in-



Canada Car Company, Limited, Montreal—Arrangement of Tools in Forge and Smith Shop.

deed well equipped. In the planing mill there is a 7½ ton Niles electric traveling crane of 68 feet span, and a similar one does duty in the matching room. Two cranes of the same capacity and about 24 feet span do the heavy carrying in the forge shop. Scattered throughout the works, wherever they will be useful, are about twenty jib cranes of from 1 to 2 tons capacity, and a number of smaller cranes will be installed to look after the lighter work. These jib cranes were furnished by the Northern Engineering Co., of Detroit.

A feature that must not be overlooked is the heating system, which has been said by many experts to be the finest in any similar plant in the world. Throughout the works an even temperature is kept. the perfect working of the system reflecting great credit upon the Miller Heating Co., who installed it.

Speaking generally, the machinery in this plant is laid out in an almost ideal manner, and the ease with which the material goes from one process to another until the finished product issues from the works, has been remarked upon by almost every visitor.

AN EVIDENCE OF PROGRESS.

KER & GOODWIN, of Brantford, Ont., machinists and machinery manufacturers, have been in the supply and machinery business for only eight years, but in that time have built up a trade that at first though merely local has extended to all parts of the Dominion. A little over two years ago they turned out their first goods in the way of manufactured articles and since that time have been steadily advancing. Early in the year 1905 it was recognized that increased premises and further facilities for manufacture should be obtained to keep up with the expansion that had been in progress for some time. A new factory was proposed and on April 10 work was commenced on a new plant on Colborne street, Brantford. Such good progress was made that on August 1 the old premises were vacated and Ker & Goodwin became established in their fine new quarters. A further complement of machinery was added. From that time work has been rushed, and as yet there is no sign of overtaking business already on hand.

The new building is 70 x 40 feet, solid brick, on cement foundations, of the slow burning mill construction type. It is two storeys high. In addition to this there is a separate boiler house of the same material, 18 x 19 feet.

On the ground floor the front part is

attractively divided off into office and stock rooms, the former being neatly fitted up and installed with all modern office equipment. In the stock room are kept the small supplies that are in constant demand in a machine shop of this kind. The remainder of the ground floor is devoted to a machine shop. The upper story is used entirely for patterns and storage. The power house contains besides a suitable steam engine and boiler of ample capacity, a case hardening furnace, and an air compressor. The machine shop is equipped in a complete manner with different styles and patterns of lathes, light and heavy drills, milling machines, drill grinders, universal tool grinder, shapers, etc., being ample to deal with the varied demands made upon them in these works.

Fig. 1.—Threading Jaws. Ker & Goodwin, Brantford.

Fig. 2.—Turning Screws. Ker & Goodwin, Brantford

Besides a large variety of repair work of all classes, both light and heavy, this firm have gone extensively into the manufacture of a special line of chucks of their own design. These have been placed on the Canadian market recently and are meeting with a splendid reception from the trade. It is intended to branch into other lines later, and following out the energy and capability already shown, no small success is assured for the future.

The firm consists of Messrs. J. Ker and A. Goodwin, two young men whose enterprise is shown in their undertakings. The illustrations given herewith may leave some impression of the work that is being done in this new plant.

BIG POWER DAM PROGRESSING.

Work on the water power development at Fort Frances is being pushed forward as rapidly as possible. Two large towers have been erected on either side of the river and the aerial tramway placed in position. The machinery required for construction purposes is now installed and in operating order. 12,000 barrels of cement have arrived and work on this important piece of construction will be completed at as early a date as possible.

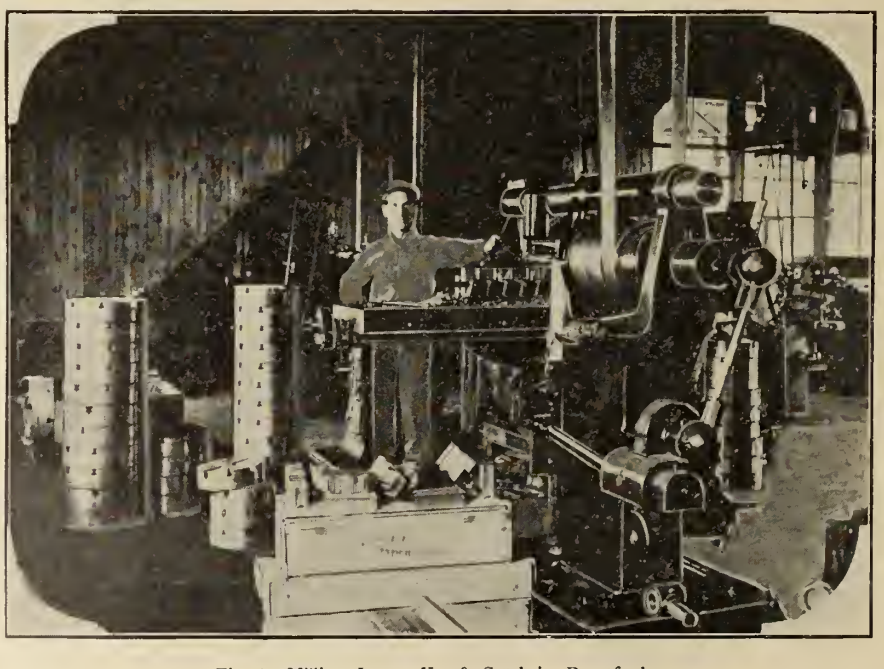

Fig. 4.—Milling Jaws. Ker & Goodwin, Brantford.

A RESOLUTION.

Whatever your present self may be, resolve with all your strength never to degenerate thence.—C. Bronte

The Allis-Chalmers Steam Turbine

BY the recent starting up of a steam turbine at the Washington street power house of the Utica Gas & Electric Company, Utica, N.Y., attention is called to the fact that this is the first turbine to be put into operation by the Allis-Chalmers Company, who have recently entered the steam turbine field. The turbine outfit installed at Utica is shown by the accompanying Figure 1.

This turbine is rated at 1,500 k.w. normal load, and runs at a speed of 1,800 revolutions per minute. It is direct coupled to an Allis-Chalmers 2-phase, 60-cycle revolving field alternator, operating at 2,500 volts. The unit has a continuous overload capacity of 25 per cent., with a 3-hour 50 per cent. overload capacity without exceeding a safe generator temperature, and capable of a 100 p.c. safe momentary overload. Artificial ventilation by means of an

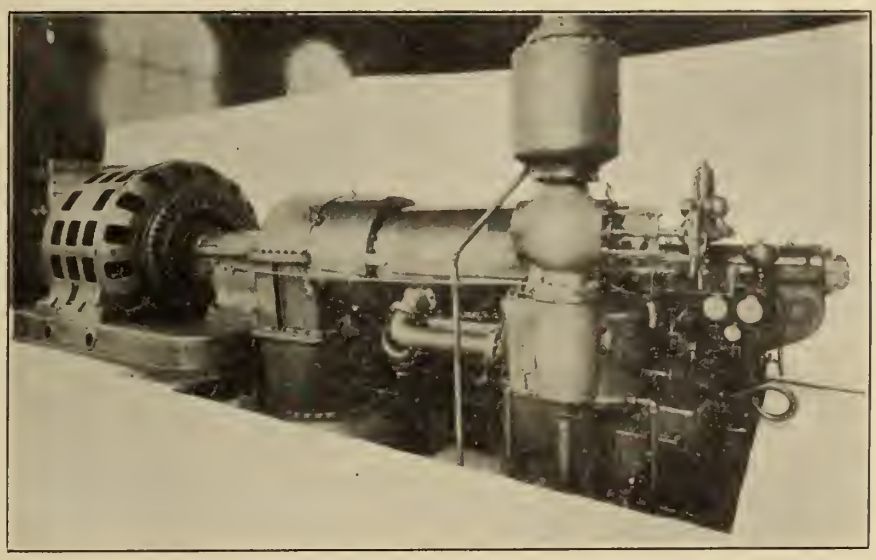

Fig. 1.

electrically driven fan blower will, however, enable the unit to be run safely beyond its rated overload capacity.

Features of This Turbine.

The turbine follows the well known Parsons type which has proven itself eminently successful in numerous installations both here and abroad. The Allis-Chalmers construction, however, embodies a number of features which are new in this country, and which are claimed by the builders to be distinct improvements.

The chief distinguishing feature of this construction is the blading, which, while it is of the Parsons reaction type as regards the principle of operation, differs in mechanical construction in a number of essential details.

The roots of the blades are formed in dovetail shape by special machinery, and are inserted in slots cut in foundation or base rings; these slots being formed by special machine tools in such a way as to exactly conform to the shapes of the blade roots. The foundation rings themselves are of dovetail shape in cross section and are inserted in dovetailed grooves cut in the turbine cylinder and spindle respectively, in which they are firmly held by key pieces, much in the same way that the well known "Lewis" bolt is fastened. In order to further insure the integrity of the construction, the key pieces or rings after being driven into place are upset into undercut grooves.

Another noticeable feature of the blading is the method of reinforcing and protecting the tips of the blades. This point in steam turbine design is one upon which much thought has been expended by various inventors, and the Allis-Chalmers Company claim that the construction employed by them successfully solves all difficulties. In forming the blades a shouldered projection is left at the tip. This is inserted in a slot punched in a shroud ring, the slots being punched by special machinery in such a way as to produce accurate spacing and at the same time form the slots so that they will give the proper angles to the blades independent of the slots in the base ring. After the blade tips are inserted in the slots in the shroud rings they are riveted over by specially arranged pneumatic machinery.

The shroud rings are made in channel shape, with outwardly projecting flanges which, after assembly in the turbine,

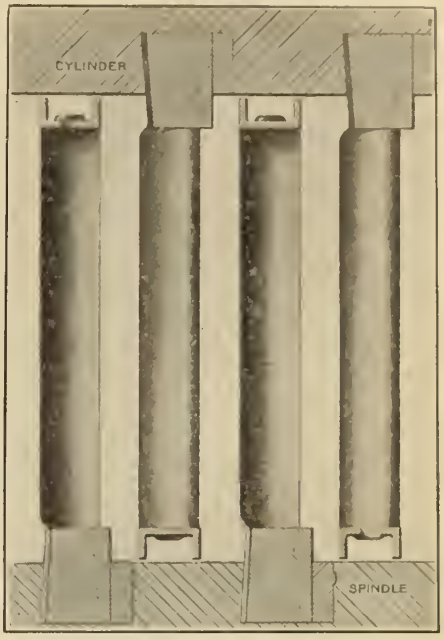

Fig. 2.

are turned and bored to give the necessary working clearance. The flanges of the channels are made so thin that, although amply sufficient for stiffness, the shroud ring does not have the disadvantage of a solid shroud which acquires a dangerous temperature by friction in case of an accidental contact of the rotating and stationary parts. It is claimed for this construction that the blades are stiffened against the effect of vibration in a much more substantial manner than by any other means thus far employed, while the use of a protecting shroud ring enables the working clearance to be made smaller than in the case of naked blade tips, without danger in case of accidental contact, thus reducing the leakage loss to a minimum, the leakage past the blade tips being the principal source of loss in the steam turbine.

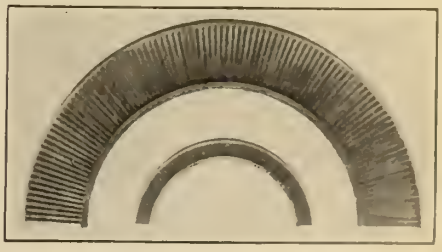

Fig. 3.

As to the safety from damage in case of accidental contact, it is claimed that this has been proven by experiment with

actual blading, by throwing the bearings out of centre so as to produce contact, without detrimental results. An incidental advantage claimed for this construction is that if by chance a blade should prove defective, it is so held in place by the shroud ring that it cannot possibly work loose and produce damage.

By the method of construction described, the entire blading is produced by machinery, thus eliminating the personal equation which enters into blading done by hand work, which depends upon the skill of the individual workman. Besides ensuring that every blade is securely fastened, all blades are necessarily set at exactly the designed angle and pitch, the openings between blades, upon which in great part the economical performance depends, being absolutely uniform. The blading is made up in half rings in the blading shop and is carefully inspected before being inserted in the turbine.

Figure 2, which was photographed from a drawing, shows the general scheme of the blading, illustrating the

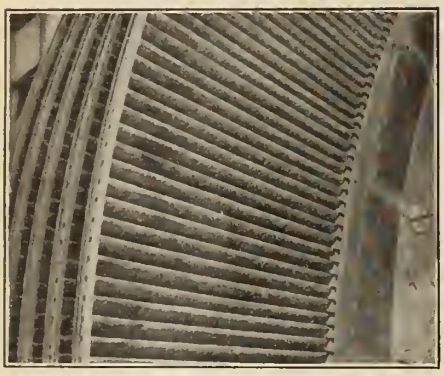

Fig. 4.

method of fastening the blades as well as the channel shaped shroud ring. Figure 3 shows two half rings or blades ready for assembly in a turbine; these half rings being respectively the smallest and largest ones, used in a turbine of the size installed at Utica. Figure 4 is from a photograph of blading, showing the substantiability of the construction as well as the uniformity of the work. Figure 5 shows a turbine spindle of the same size as that of the Utica turbine, this photograph having been taken in the West Allis shops of the Allis-Chalmers Company.

Another special feature of this turbine will be noticed by referring to Figure 5, viz., the absence of the usual low pressure balance piston, the photograph showing only two balance pistons instead of the three pistons formerly used in this type of turbine, where it is said to have been found difficult to produce a balance piston of the size required for balancing the low pressure stage of the turbine and at the same time make it sufficiently rigid to run with the necessary small working clearance. In the Allis-Chalmers construction there is, however, a third balance piston, but instead of being at the high pressure end of the turbine, as formerly arranged, it is at the low pressure end, and as it is smaller than the large end of the spindle it is hidden from sight in the photograph. By making this piston in such a way that its circular area is equal to the annular area of the pistons used in the older construction, the low pressure balance piston is made much smaller. Instead of reducing the leakage past this piston by means of "dummy packing," as in the high pressure and intermediate pistons, and as used in the low pressure pistons of the older construction, a labyrinth packing of radial baffling type has been adopted, thus eliminating small axial clearance in this turbine. A considerable advantage is claimed for this construction in permitting of the use of smaller working clearances in the high pressure and intermediate balance pistons.

There are a number of other points of improvement claimed for the Allis-Chalmers construction which will not permit of description within the space of the present article. These include details of spindle construction, governing mechanism, lubrication, and other minor features.

The alternating current generator of the Utica outfit also is deserving of more description than the present article will allow. Perhaps the most noticeable feature of this generator is the substantial design of the revolving field, providing great strength and at the same time giving the thorough ventilation which is essential. Particular attention has been paid to the insulation, as may be inferred from the fact that the armature (Figure 6) was subjected

Fig. 5.

to an alternating current insulation test of 10,000 volts for the period of fifteen minutes. This generator was built at the Bullock works of the Allis-Chalmers Company at Cincinnati, where the generators for all of their other turbine outfits are being built.

COMPETITIVE HIGH-SPEED STEEL TEST.

SOME idea of the number of high-speed steels on the Canadian market and the keen competition existing amongst the different manufacturers and agents thereof, has been shown lately at the C.P.R. Angus shops, Montreal. The management decided to find out from actual tests, in the well equipped machine shop, the merits and demerits of the different steels for the particular work required of them in locomotive building. It will be a surprise to many to know that no less than twenty-two different grades and brands were submitted. The tests carried on were of a more searching character, so that the officials should be fully satisfied when the final decision is reached.

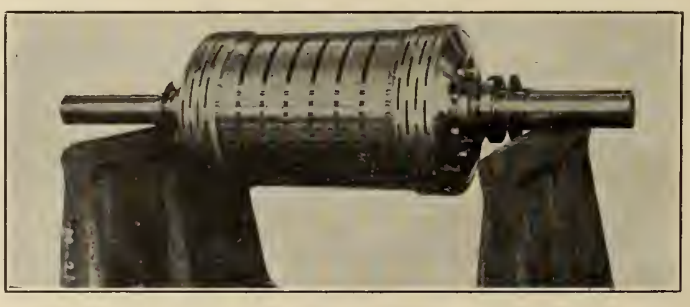

Fig. 6.

AN IDEAL.

Begin, live, aspire, realize the best ideal of the moment, and this earnest effort shall lead the way to greater achievement.

—H. W. Dresser.

An Interesting Meeting.

THE members of No. 1 Canadian Association of Stationary Engineers, together with their friends, were treated to a very interesting blackboard talk by Mr. James Milne, manager and chief engineer of the Underfeed Stoker Co., Toronto.

The matter treated on consisted of three headings (1) the amount of water required for condensing purposes, (2) from and at 212 degrees, (3) heating by electricity.

Under the first heading Mr. Milne treated very fully, and showed by successive stages as to how certain formulae were arrived at and brought out the following rule:

To 1114.4 add 3-10 of the temperature of the steam entering the condenser and from the sum subtract the temperature of the hot well. Divide by the difference between the initial and final temperature of the injection water, and the answer will be the number of pounds of water required per pounds of steam for condensing purposes.

Under heading No. 2 Mr. Milne treated on boiler testing and showed that in order to make proper and fair comparisons between boilers operating under different conditions as to feed temperature and pressure, the only correct basis was from a feed water temperature of 212 degrees to steam at 212 degrees.

Prior to commencing this section, a heat computor, designed by Mr. Milne, was distributed to the members present, for one of which Canadian Machinery begs to thank the Underfeed Stoker Co. This computor is for determining practically all calculations pertaining to steam. Once the feed temperature and gauge pressures are known by a movement of a slide, the factor of evaporation and equivalent evaporation from and at 212 are determined at once. Every engineer should have one.

The talk on heating by electricity was certainly interesting and showed quite conclusively that even when electric power was delivered from Niagara to Toronto there was little hope of the houses ever being heated by same.

With electricity at 2 cents per kw, it was proven that it was seven times more expensive than heating by steam or hot water system, using hard coal, and using soft coal it was thirteen times more expensive.

After the lecture was over Mr. Milne received a very flattering testimonial from Mr. A. M. Wickens, which was seconded by Mr. Charles Mosely.

Mr. Milne leaves for British Columbia at the end of January to assume the position of general superintendent of the B C. Railway Co., and the C.A.S.E. wishes him every success.

Prizes to be Awarded.

EVERY year the Canadian Society of Civil Engineers awards four prizes for papers presented to the society by student members. These should arouse an enthusiastic interest on the part of every student member and cause him to set out with the idea of winning one of these prizes of twenty-five dollars. During the past they have been won for the most part by McGill men, the student members from other institutions not having competed to the same extent. December 31 is set as the last day these papers should be in the hands of the secretary, Prof. C. H. McLeod. It is hoped that anyone who has missed the opportunity this year will get busy and whether he proposes entering the field of civil, mechanical, electrical or mining engineering that he may have an ambition to win this prize another year.

* * *

Geologist Honored.

At the meeting of the Mining Society of Nova Scotia held at Halifax, Mr Hugh Fletcher, B.A., of the Geological Survey Department, was presented with an address accompanied by a gold watch, chain and aneroid. The address characterized Mr. Fletcher as a gentleman who by his untiring energy and patience has been most successful in causing the unlocking of nature's secrets and throwing open the door to those who wish to grasp the opportunities.

* * *

Provincial Mining Society.

At the recent Ontario mining conference it was decided to form an independent provincial organization, as the miners of different sections had decided to form local societies. The report of the committee on organization favored this and the general body seemed to be of the same mind. The name "Ontario Mining Association" was proposed. Residents of Ontario and non-residents interested in mines in the province to be eligible for membership. The annual fee, it was suggested, should be $2; the officers, president, vice-president, secretary-treasurer, and nine others, the whole to form the executive. The first executive should, it was recommended, report upon a constitution. The question of affiliation with the Canadian Mining Institute was discussed but nothing definite was arrived at.

* * *

Electrical Engineers Meet.

The Toronto branch of the American Institute of Electrical Engineers met at the School of Practical Science on the evening of December 22. An interesting paper by Mr. E. B. Walker on "The Booster Control of Storage Batteries" was read.

Awarded Gold Medal.

Interesting news has been received by the Chicago Pneumatic Tool Co. from the Jury of Awards of the Liege Exposition to the effect that they had been awarded both gold and silver medals for their exhibits. The gold medal was the highest given for pneumatic tools and appliances and the silver medal was granted for Franklin Air Compressors. This is a high tribute to the class of goods manufactured by the Chicago Pneumatic Tool Co.

CANADIAN
MACHINERY
AND MANUFACTURING NEWS

A monthly newspaper devoted to machinery and manufacturing interests, mechanical and electrical trades, technical progress, construction and improvement, and to all users of power developed from steam, gas, electricity, compressed air and water in Canada.

A HAPPY NEW YEAR.

TO all the readers of Canadian Machinery we extend our best wishes for a Prosperous and Happy New Year, and express the hope that it may see your expectations fulfilled and your ambitions realized in so far as that is possible within one year.

No people living to-day have greater cause for thankfulness, for the blessings of the past, than the citizens of the Dominion of Canada. No people can look forward into the year upon which we are now entering with greater hope and confidence. All this should go towards making thankful hearts, a contented people and promote a high sense of citizenship. With what the coming year promises the people of Canada generally, there is every indication of a further tide of prosperity and we hope that every reader of this paper may share it in no small measure.

UNION OF CAPITAL AND LABOR.

SO much is being said from time to time on this problem and the difficulties confronting those most vitally interested that little else seems possible of expression. As long as the employer feels it is an imperative duty to keep his workmen under his thumb and does his best to accomplish that end, and as long as the workmen feel antagonistic to the men whose brains and foresight have created the industry in which they are engaged, little can be hoped for in the way of progress Different systems of payment of wages have their special advantages and drawbacks.

The nearest solution of this vital question seems to have been reached by the manufacturing industry at the head of which is Mr. Theodore Cooke Taylor, member for the south-east division of Lancashire in the British House of Commons. In an address before the Canadian Club some weeks ago Mr. Taylor explained his position and the position of his company on the subject. The industry in question is a woollen manufacturing business that has been in the family for four generations and employs 600 hands. They consider that the employees have a definite claim on the employers, and as such are entitled to share in the profits at the end of each year's business. Following out this they set aside every year a proportion of the profits. These are given to the workmen in the shape of one pound shares, which have no voting power, but upon which dividends are paid. Thus the interests of capital and labor are made identical, as every dollar profit to the firm means a certain amount to the men. This has passed the experimental stage, having been given thirteen years' trial, so that Mr. Taylor had ample chance of studying any drawbacks the system might offer. He stated that in his opinion it was the only method of solving the problem between capital and labor, and no doubt there is sound logic in his argument.

Of course such is more possible of being put into execution by an old established firm that has had every opportunity to know its exact position than with comparatively newly established industries such as represent the large majority in Canada.

With the adoption of this system the golden age of labor would be an accomplished fact. As this country increases in wealth, in population and in developed resources, many of the firms established and on a sound basis to-day will probably before long be in a similar position to the English industry mentioned. As a matter of general progress in manufacturing, the establishment of the profit sharing system, as carried on in England, would elevate the standard and give an added tone to industrial affairs in Canada.

FAKE INVESTMENT PROPOSITIONS

SOME time ago Canadian Machinery drew attention in its editorial columns to the preposterous claims which were being put forward in the daily press by the promoters of a company destined to manufacture a motor of surpassing excellence. The Mite-e-motor was the name of this wonderful machine and the company's prospectus which was published in commanding type by many daily newspapers throughout the country, modestly remarked that it was "the most marvelous invention the world has known." A company known as the Canadian Turbine Propulsion Power & Light Company was organized to produce this great machine, and the public were given the privilege of purchasing stock in the company at five dollars a share.

At the time (about a year ago) a representative of this paper attempted to get full information on the design of the motor, but without success, as the company's promoters always had a score of excuses for not showing the working model or the detailed drawings. Naturally the conclusion arrived at was that the claims advanced for the Mite-e-motor could not be substantiated, and that an

effort was being made to entice the ignorant and unwary into sinking their money in this fictitious company. Our readers were warned against being gulled by the specious promises of the promoters and the Canadian Turbine Propulsion Power & Light Company was challenged to produce a machine that would fulfill anything approximating the claim advertised for the Mite-e-motor.

Since that time the wisdom of our course has been shown, as absolutely nothing has been done to place on the market "the most marvelous invention the world has known." The Canadian Turbine Propulsion Power & Light Co. has quietly dropped out of the limelight, and if it were not that a rank fraud has been prepetrated on the investing public, the subject might be allowed to rest.

But it is beyond question that some people have been made to suffer by putting money into a concern which they thought would manufacture an article tending to revolutionize the industrial world. It is also quite conceivable that a goodly proportion of these investors could ill afford to lose their money. But how can they hope to have it restored ?

It is high time that some move was made on the part of our legislators to protect the public against these harpies of finance, who ruthlessly take advantage of those who lack the knowledge requisite to a correct understanding of such wild-cat schemes. Under existing laws fakirs can with impunity float companies that exist on paper only, and always some section of the country is robbed of hard-earned money. The disclosure of the real status of these fake companies never seems to come until it is too late. And the pity of it is that the "men behind" escape the clutches of justice, and are emboldened to still further exertions of a similar character.

Within the past few years Canadians have been growing richer, and in consequence the harvest of fake promoters has been great. Everywhere the greatest ease has been experienced in securing subscriptions to stock in questionable investment companies of all kinds, mining companies, and, as in the case under discussion, industrial companies. But the great mass of our people must soon demand that action be taken to prevent swindlers from preying upon their bank accounts. The public are protected against pickpockets and housebreakers. Can larger and bolder operators be safely neglected ?

LONG POWER TRANSMISSION.

ONE hundred and eighty-two miles is the enormous length of the Mexican Light & Power Co.'s new transmission line over which power was transmitted for the first time early in December. This is an engineering feat of no small significance. Interest is added to the fact when it is known that the above company is entirely Canadian and the development referred to due to Canadian brains and capital.

MINERAL PROSPECTS.

SINCE the mining boom in British Columbia a few years ago, and the Klondike gold discoveries, there has been a steady though somewhat less spectacular movement in mining affairs in Canada. Discoveries made within the past two years have proven beyond a shadow of a doubt that Canada's future as a leading mining country for years to come is assured. From the Atlantic to the Pacific there are to be found minerals comprising almost the entire line of commercial metals, some of which are the richest of their kind. From the coal and iron of Nova Scotia and Cape Breton to the gold of the Klondike these will be wealth produeers for the present and future generation.

The report of the electric smelting operations being carried on under Government supervision at Sault Ste. Marie giving every indication of a commercial application and proving the economy of electric smelting stimulates the mineral strength and wealth of Canada in no small measure. With the inauguration of this process on a commercial basis the water powers of the north will be harnessed to reduce the mountains of iron ore and make Canada the greatest iron producing country of the world.

In this country are to be found nearly all the mica in America as well as the richest veins of asbestos ever discovered. The recent startling finds of silver in the Cobalt district show to some extent the possibilities of Northern Ontario mining, these latter being conceded the richest finds of silver yet made. The nickel of the Sudbury district is already famous, the enormous amount of which has never been duplicated in the history of the mineral discoveries of the world.

Some idea of the value of Ontario's minerals during the nine months ending with September is given in the report of the Director of the Bureau of Mines, who uses for the purpose the selling price of the products at the mines or works. The total value of these for the nine months mentioned is given as $9,000,000, which means that as refined metals these ores estimate an amount equivalent to twice that at least. Of this amount $3,890,000 represents nickel and silver. With such an enormous production of valuable ores it is a strange fact that as far as present development goes these cannot be refined in this country. Such plants would pay for themselves over many times. There is every reason for this and the mining interests of our country demand that such should be done.

The recent mining conference on the part of these interests in Ontario should result in a more satisfactory state of affairs in that province and result in

SMALL AUTOMATIC WORK.

IT is nothing short of marvellous the way automatic machinery is being designed and manipulated to turn out the finest and most accurate work demanded. Within the past month there came to the writer's notice a piece of work done on a Brown & Sharpe automatic machine that for smallness of size and accuracy has probably not heretofore been paralleled. It was a watch pinion spindle less than one-quarter inch in length. The body of the spindle was twelve one thousands of an inch in diameter. The most notable feature on this minute piece of work was the fact that it had a 60 deg. taper on either end, and, what is probably almost as remarkable, the fact that where cut it forms a perfect centre. This is obtained only by the extremely accurate tooling done, as well as by the fine regulation of the machines, as besides being tapered at either end the body is of two sizes, the larger extending about one-third of the length. It goes to illustrate the wonderful strides that have been made in machine tool adjustment and mechanism in recent years.

Rungs in the Ladder of Success

By The Editor.

EVERY man, young or middle-aged, in the possession of his faculties, should be keenly alive to the boundless scope and breadth of possibility that the moment offers. High up in the ladder the rungs are empty and await an occupant. The present holds out for you what no other decade could near approach.

Do you realize the fact?

A brief reflection would make this a conviction and, going further, quicken it into action.

Possibly not the success of the millionaire nor the statesman may be yours, but surely the real, genuine, satisfying success, the result of honest and well-directed effort, awaits you. This is obtained by making the most of one's self It means to those who have not made the attempt an enjoyment in being hitherto unknown.

For a New Year's resolution along the line of things that go to make success, let us suggest some reflection on the subject of the nobility of labor, having higher ideals, being confident, determined, persevering, industrious and enthusiastic. With these as an incentive no man can hold you back.

Nobility of Labor.

The mechanic is the great producer of the day. He is daily adding to the wealth of the world and should be proud of the fact. When a man reaches the state when he no longer works with his hands and belittles honest toil, he occupies a ridiculous position. He has forgotten that he is dependent upon the men who work for any measure of comfort he may enjoy. Suppose all the mechanics in the world were to stop work. How long would the wheels of commerce or industry revolve? Not many hours. Let every mechanic hold up his head and look the whole world in the face, feeling that he is an important and indispensable factor in the commonwealth. The writer knows the call of the 7 o'clock whistle, the clink of the time check and the line-up on pay day, and is glad of it.

Ideals.

No one has yet climbed higher than his ideal. No one ever shall. If you have not accomplished what you feel you might have, all the more reason for aspiring. If you are satisfied, then it is time to take Dr. Osler's prescription, whether you be twenty or three-score and ten. Look at the example of Richard Arkwright, the inventor of the spinning machine, and take heart. At the age of fifty he set to work to learn English grammar, writing and spelling, working often from four in the morning until nine at night. Was he justified? See the result. Eighteen years later he was at the head of many manufactories, had risen to the position of high sheriff of Derbyshire and shortly after was knighted by George III.

With no ideal beyond the daily round, one is as the miner with his torch extinguished, groping in the dark and unable to accomplish anything. If any of us have been living in the quarry-slave realm of thought, let us rise above it with all the strength of mind and body that we possess.

Confidence.

More perhaps than any requirable attribute that engenders success, confidence in one's ability to achieve is necessary. This, coupled with a fair amount of assurance, has caused many a young man to climb the ladder when his equally capable companion has failed. Meekness is misunderstood for weakness and a lack of confidence is the forerunner of failure. Be confident.

Determination.

Despondency begets madness, but determination is the key-note of accomplishment. How the world stands by for the determined man! He is the great explorer or navigator, the successful general or the powerful captain of industry. This is the attribute that made a Napoleon and a Wellington, and due to this the victorious Japs achieved so much. A determined man is a tower of strength. Be, therefore, determined.

Perseverance.

History's pages are filled with the records of men winning their laurels through sheer perseverance. It is not necessary to go beyond the realm of the mechanical world to find striking examples. George Stephenson spent fifteen years working on the improvement of his locomotive before meeting with his triumph at Reinhill. Another shining light in this direction was James Watt. The latter would not acknowledge defeat and after 30 years of investigation and toil he brought the steam engine to mechanical perfection. Let us keep these examples before us when our courage lags or our ardor cools, and resolve, as they well must have, neither relenting nor hesitating until we have improved our present position. Persevere.

Industry.

Well directed industry brings its own reward. Unfortunately much individual industry is misdirected and unproductive. Patient plodding application without the accompaniment of thought never brings a person to an exalted position. On the other hand, however bright the mind or clear the conception, the lack of industry is fatal to success. Be industrious.

Enthusiasm.

Enthusiasm is one of the hardest qualities to cultivate and maintain. It is one of the least common. The enthusiastic man leads. He is a moulder of opinion. He is a factor in the community and in the workshop. He commands attention. He is influential. He rises and progresses. He soars above his fellows. He is a marked man. Many people shrink from being enthusiastic for fear of attracting attention. If you are on the right track, however, every throb of enthusiasm opens the channel to higher things and to a position where one's abilities have fuller scope. Cultivate enthusiasm.

THOSE WHO FAIL.

It is ofttimes true that those who seem to fail are indeed more successful than those with whom all things appear to go well. It is not always the people whose names are on everybody's lips and who get frequent mention in the newspapers who are doing the most good; ofttimes those of whom little is heard, who work away in quiet and obscurity, are doing more to bless the world than those who seem so conspicuous. A writer tells of passing through a meadow and finding the air full of fragrance. Yet he saw no flowers and wondered whence the fragrance came. In his quest he found that beneath the tall, showy grass multitudes of little lowly flowers were growing, hidden away out of sight, yet pouring forth sweet odors. It is often the lowly lives that do the most to sweeten the world. —Ex.

Designing a Molding Machine

By T. C. Robertson.*

THE development of the molding, together with the flooring machine, has contributed more towards the rapid construction of buildings, than, perhaps, any other feature in the house building line.

The combination of molding members now used in producing massive designs and beautiful effect, calls not only for a large combination of knives upon the molding machine, but draws largely upon the ingenuity and resources of the operator. It is not enough that the operator should be a mechanic and somewhat of an artist, but must have some knowledge of the construction of the machine he is running, so that the purpose in the mind of the designer may be carried out and the best results obtained.

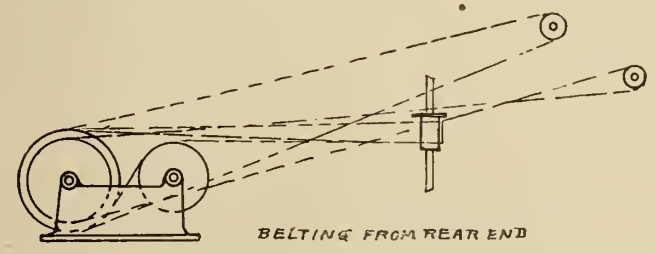
Many claims are put forward by the various makers, but the main difference between machines of different designs is one of convenience rather than of principle. During the years in which the molder was in process of evolution many builders in aiming at cheapness built their machines too light, having lost sight of the fact that to lighten the parts reduces its factor of efficiency. Experience of later years proves that high speed machines require weight to impart solidity and permanency, thus producing a higher grade of work. Another important factor in the building of this machine is the many improvements calculated to facilitate the work. This has become imperative, owing to the demand for a great variety of work, calling for rapid adjustment and the greatest convenience in operation.

A mistake frequently made by many machine builders is the enforced use of many wrenches. In putting on time-saving appliances the manufacturer will spare no expense to have bolt heads and nuts used many times in a day, as near one size as possible, so that the whole range of adjustment may be covered by as few wrenches as possible. Another means of saving time which has recently been adopted by builders is the substitution of hand wheels for wrenches, by which not only is quicker adjustment attained, but much twisting off of bolt heads and stripping of threads is avoided. The bolt threads of all adjustments should be kept oiled and friction surfaces kept clean, which will not only prolong their life, but assure more satisfaction in every way. Wrenches should be case-hardened, particularly those that are much used, as they will soon be compressed out of shape.

If possible all bearings should have cap screws of same size, and a socket wrench provided to fit them; in fact all set and cap screws should be as uniform as possible, so that the number of wrenches be limited.

The several adjustments which govern the top and bottom cutter heads, as well as the side heads, have received a good deal of attention by designers. All these movements should be made from working side of machine if possible. The side heads should, of course, be attached to bed or table, so that in raising or lowering they may always maintain the same relation to each other. They should, also, have both lateral and vertical adjustment, as well as tilting motion.

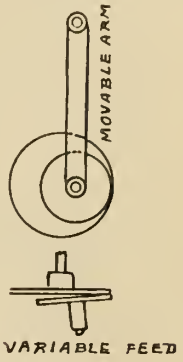
Pressure bars and pressure shoes employed in keeping material firmly upon table while cutter heads are in operation, have of late been remodelled and made more effective. They should be so constructed as to straighten as far as possible and hold firmly stock which may be more or less warped. For convenience in getting at cutter heads, it is better to have them so designed as to swing entirely out of working position.



BELTING FROM REAR END

Much has been said and written of late concerning position of top and bottom cutter heads in relation to finish of stock. Many contend that the best results are obtained by finishing stock pattern side up; others contend for finishing pattern side down. Both sides have strong advocates, and in order to satisfy customers manufacturers are building them both ways. In some instances molding machines are built with three cutter heads, besides side heads, one before and one behind centre top head, which enables operator to choose either method of finish.

An important feature of the molding machine is an improved feed of friction design, which of late has found strong advocates among mill men. This consists of two disks with faces placed opposite each other, the one perpendicular and placed upon driving shaft, the other with face oblique and movable by suitable mechanism across face of perpendicular one. In applying this method of drive care must be taken to have sufficient speed upon driver, so that plenty of power is transmitted to driven, and hence to feed rolls. A controlling lever convenient to operator enables him to vary feed instantly, without stopping machine. If friction disks are large a wide range of feed can be obtained.



VARIABLE FEED

The belting of molding machines has recently undergone changes similar to methods employed in surfacing machines. The placing of countershaft at rear end and separate from machine leaves space in front entirely free for stock and operator, besides giving any length of belts required. Objections may be raised to this method owing to countershaft being in the way of finished stock being delivered from machine, but this can be easily overcome by placing cover over pulleys directly in line with bed of machine.

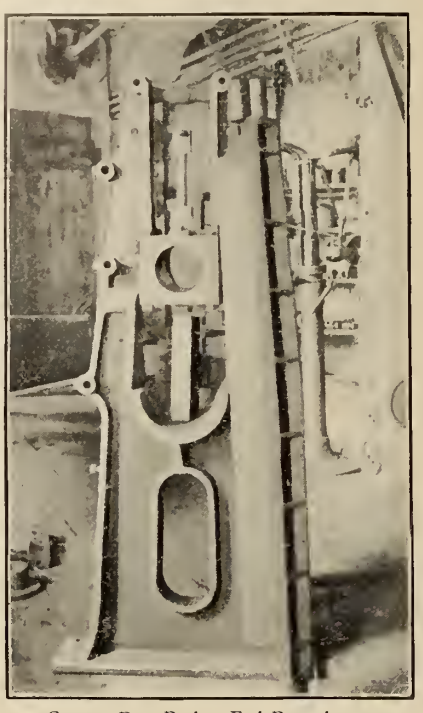
Much might be written concerning the minor but still important details of molding machine construction. Experience shows that too much care cannot be taken to insure durability, perfect alignment, perfect balance of cutter heads, tight babbit in bearings, in short every precaution taken to satisfy the most exacting operator.

* Chief Draughtsman, MacGregor-Gourley Co., Limited, Galt, Ont.

Burning Expensive Parts Together

By Edwin Krug.

QUITE recently a large housing and scraping bar for a huge paper machine for the Bird Paper Co., now locating in Hamilton, was broken in unloading same from the cars, through the cause of a faulty tackle giving way and letting the parts fall several feet from an incline they were being let down. The housing shown in the accompanying photograph was broken at the mark shown, and the end broken off the scraping bar. To replace these parts quickly was quite a pressing matter. An accurate repair was imperative, if made, and the machine coming from the Eastern States, to put in a new one meant a very expensive undertaking, as the housing was planed on the base and in and outside, drilled accurately to fit the different levers, brackets, etc., besides the lower being babbitted a given height from the base to suit a mammoth ground roll 16 inches in diameter between bearings, and shouldered down at the bearings to 9 inches and about 8 feet long. The upper roll was about half the diameter driven at a ratio of 2 to 1 by spur gears, and was supported by two large babbitted boxes, gibbed sides to fit snug on the insides and gibbed to fit sidewise so as there would be no lateral motion in elevating and lowering, which was done by hand nuts and levers, fulcrumed from the housing to a standard fastened to the upper half of the boxes, and long elevating screws, the hand nuts to lock same when the required height was reached. The large rolls were in the housings when they fell, and this section including a subsidiary roll and suitable brackets to support it weighed six tons. nine hundred pounds. Mr. Geo. Coombes, of the well known firm of Kerr & Coombes Foundry Co., and the writer were called in consultation on the subject, and after looking over the ground, which, by the way, was over a considerable part of the machine, we decided it could be burnt together successfully and to this end we dismantled the machine and brought the offending parts to the foundry. Probably the average reader will not understand this operation, and a little insight into it may



Scraper Bar, Broken End Burned on.

prove a benefit. Usually the parts to be burned are fastened together securely, then bedded in the sand, and a place is left open like a gate above the broken place to pour in the molten metal and enough iron poured on the part or parts to be burned to burn the new section in, and a gutter is dug to let the molten mass run into until the required amount, which depends on the size of the casting, has been poured in. In this case about six hundred pounds were required to burn in the new section and a rib was left to help strengthen the same. In preparing this casting for the foundry we were unusually fortunate, no extra holes being required to be put in. The sides of the housing had large cores through, and one side of the housing was still intact, then we had the gibbed box referred to previously to space us accurately, and put long bolts through the cored places and clamped each side of the bearing, testing same from end to end to make sure the two were perfectly parallel. The scraper box, the broken end of which is shown in photo, was burned on also, but a new piece was made and burned on as the end was turned and bored to swing on a centre stud and must be the correct distance between the shoulders, and the break was exactly at the square shoulder. To burn on the old piece and have same come true a nice faced shoulder was out of the question, so a pattern and casting for a new end was made long and large enough to permit being laid out true with the scraper edge and face. Then for material on the shoulder the bar was bedded in the sand the usual way and moved back after taking the impression one-quarter inch, so when burned on the shoulder was then faced correct width, the new end turned up and not one blemish was noticeable, the new piece standing roughing off 1-2 by 1-32nd inch, and then finished, steady-rested and this heavy piece unequalling balanced swung and bored to required size and depth. This foundry makes a specialty of burning pieces together and is remarkably successful in this line, having burnt thousands of dollars' worth of parts together, which have stood the strains they are subjected to for many years and are still doing so.

Making Cold Drawn Shafting

LESS than a year ago no cold-drawn shafting was made in Canada. Now there are in Canada two large plants, one already manufacturing and the other rapidly approaching that position. The requirements of any factory always constitute with it a large amount of shafting, and upon this and its proper adjustment and bearings depends to considerable extent the power economy of operating the plant. Very special machinery is required for the manufacture of cold-drawn shafting, and the equipment seen in the plant of the Union Drawn Steel Co., at Hamilton, is a revelation to any one not conversant with this line of manufacture. Probably in no other line of metal working machinery are such long beds required nor such lengthy and ponderous driving gears.

The raw material of the cold-drawn steel company's plant is the finished product of the rolling mills. The first operation consists of placing the bars to be drawn in a bath, where they are thoroughly cleaned. The operations are few but all important. The material is then taken to one of the heavy drawing machines and drawn through a solid die of the exact size correct to 2-1,000 of an inch. From this machine it passes through a specially designed straightening machine, and from there to the cutting-off machine, where it is cut the exact length ordered. When the length has been cut off as desired every bar is tested on live rollers the same as if it were running on centres. Any crooks

or bends that may have existed in the bar after leaving the cutting-off machine are thus removed.

In addition to the drawing machines, where any size of shaft up to three inches may be drawn, a lathe has been installed to turn shafting from 3 to 9 inches, with no limit to the length except, of course, that of the building, which is by no means of small proportion. This is the only style of machine in existence that finishes the shaft complete and ready for use after coming from the rolling mill.

It might be presumed from this that the equipment of a cold drawn shafting plant is small, but this is not the case. As the special machines required are all of enormous size, and the multiplicity of gears and belting required in running these, from the large induction motors that have been installed, is bewildering on first sight. As a particular favor and departure from usual custom, the representative of Canadian Machinery was shown through the plant mentioned, and is indebted to Mr. A. J. McMahon for the interesting insight into the method of manufacturing cold drawn shafting, whose manufacture requires not only machines of enormous power but of remarkable accuracy.

Machine Shop Costs

By G. C. KEITH.

IN connection with these articles on costs in the machine shop, the article on "The General System of Cost Keeping," in April Canadian Machinery, should be read as an introduction. These articles will contain a practical system of machine shop or factory cost keeping, and other information as costs, efficiency, and the compiling of information for the use of the manufacturer and superintendent.

It is only recently that practical and complete cost systems have been devised for computing machine shop and factory costs. In the most useful system everything must be condensed and classified and details brought to the notice of the superintendent in such a manner that with a glance he can obtain the required information and see how the work is progressing in the shop.

Many manufacturers have been content to take their selling price from others. Even in this present age producers may be found who count their selling price from the rhyme of the shop poet:

"Man and tools, shop and power,
Come to fifty cents an hour."

But these latter are not apt to be the successful manufacturers. In this age of competition each individual manufacturer must know where he stands. It does not do for him to accept other manufacturers' selling prices. His costs may not be the same. He may not have bought at the same markets, and market prices are liable to change. The supply may not be equal to the demand and there will be a rise in prices or the opposite may occur. The market may be flooded and the price will decrease. The same may be equally true of the labor market, and the price of labor may go up or down, depending on the supply and demand. It is therefore essential to a business man's success to establish a system of costs that will show him in what shape his work stands and where he is financially at any time.

The man who is making a success at farming to-day is the one who knows where he stands, how much the running of the farm is costing him, and to what his receipts amount. His cost system may be a single set of books showing moneys paid out and received. If he wishes to sell his farm he can then show the purchaser how his farm has paid, and why the price should be $60 or $85 an acre. It does not do for a farmer to know that a disc is worth $45, or another machine worth $125. It does not do for him to know that cows sell for $40 each, or horses for $175. He must know his total outlay and his income. It will not do for him to make his entries on the side of the barn, showing the sale of eggs, grain, hay and cattle. When he comes to look at his marks he finds them mixed and he does not know where he stands. He must have some system about it, and the simpler it is the better for the farmer, but it must be complete. So it is in the factory. It doesn't do for a manufacturer to know that scrap iron is worth $1.20 per 100 lbs., or a certain machine in the shop cost $75 or $575. He must be able to tell the cost of the machine or engine he is manufacturing. He must be able to tell what profits he is making, whether a certain lathe or planer or other machine is a profit or an expense to him. If an expense he can investigate and have the cause removed or the machine replaced. In purchasing a machine there must be a man at the head of affairs who knows whether a milling machine or a slotter, a boring mill or a drill, a shaper or a planer will be the most economical and profitable machine for the work to be done. It will not do to purchase a milling machine to cut out keyways and have it in use six months in the year if by buying a slotter not only the keyways may be cut but also other work may be accomplished which will keep it in use the year round. Circumstances might arise, however, when the milling machine might be more economical, for it might be used for milling articles that could not be planed.

In machine shop costs there are three divisions: (1) labor; (2) material; (3) factory expenses. The first is divided into two classes: (1) producers; (2) non-producers. The producers are the only source of income, and include only those who are working on articles to be sold. All other employes—the president, manager, superintendent, foremen, office staff, draughtsmen, tool and pattern makers and watchmen—are non-producers. They do not bring any direct income to the establishment, but are just as necessary to the success of a business as the producers. The factory could not be run without them, and if it could they would be quickly dispensed with, as the close competition of to-day would demand it. But the success of the factory depends on the personality of these men and the system they employ. The application of modern ideas to business gives more chances for a manufacturer to be a success. In determining costs, system simplifies everything, and the manufacturer who recognizes this has taken a long step towards success. In a cost system for a machine shop there are many branches, but if the shop be too small to require the number of men the offices may be successfully combined.

Under material is included raw materials for construction and plant supplies, such as reamers, taps, dies, drills, belts and belt lacing, emery, files, hammers, waste and oil. There are many other expenses which come under the third division—insurance, rent or taxes, depreciation, repairs to machinery and building, water, scrap pile, i.e., spoiled work, fuel, light, telephone, stationery, postage, telegrams, traveling expenses, freight and express.

The raw materials and factory supplies are taken care of by the stock clerk and his assistants. The productive labor is looked after by the timekeeper.

(To be continued.)

BOOK REVIEWS

Modern Turbine Practice and Water Power Plants, by John Wolf Thurso. New York: D. Van Nostrand Co.; 244 pages; $4.00 net.

The author has presented a work which at the present time will be appreciated particularly by Canadian engineers whose attention is being drawn to hydraulic power developments. In the preface it is stated that the object is to present the subject in a form adapted to the work of the hydraulic engineer engaged in general construction and not to assist the expert turbine designer. The reader is impressed with the author's familiarity with his subject and is indebted to him for a large fund of information that has not heretofore been available to the English engineer.

The first two chapters of the book are devoted to a comparison of European and American practice in turbine construction. The severe arraignment of American design and construction is largely merited, but the author's attitude appears to be more hostile than sympathetic. His argument is that as the turbine equipment of the average plant represents only about 10 per cent. of the total expenditure, it is not economy to design the rest of the installation so as to enable a cheap wheel to be used. Those who are familiar with the present practice of picking out single wheels, pairs of wheels and other combinations from the tables in the catalogues of American makers, in an endeavor to meet their requirements as to speed and power, will appreciate the author's criticisms. The author's point that Holyoke tests are misleading when made on wheels that are to be used under a high head, is well taken.

The chapters on "Classification of Turbines" and "Modern Turbine Types and Their Construction," are probably the most valuable in the book. In them recent installations in Europe and America of high-class turbines under various conditions are described and illustrated. Unfortunately, the dimensions on the drawings are in metric units. There are chapters on "Accessories to Turbines" and "Governors and Speed Regulation" that are of value. The author has also included in his work as an appendix, the notable paper on "Speed Regulation in Plants Driven by Water Power," presented by Mr. Allan V. Garratt before the A. I. of E. E. in 1899.

Chapter IV. treats of steam turbine practice.

The arrangement of the work will admit of improvement. In the first part of the book the development of the subject of turbine practice is subordinated to a criticism of American practice, and much of the matter in the first two chapters has to be repeated and enlarged upon in the third and fifth chapters. Nomenclature in hydraulic work is very confusing and as a step in the right direction, the author prefixes a list of terms and symbols.

"Modern Turbine Practice" contains much information of value to the hydraulic engineer and is probably the most valuable work available to the English reader.

Gas, Gasoline and Oil Engines, including Gas Producer Plants, by Gardner D. Hiscox, M.E., author of Mechanical Movements, Compressed Air, etc; fully illustrated by 500 engravings and diagrams contains 550 pages; price, $2.50 net. New York: Norman W. Henley Publishing Co.

The books of Mr. Hiscox need no introduction to the American or Canadian readers of technical literature, as his different editions are well known as standard authorities on the lines they cover. This volume is the 15th edition, having been revised, enlarged and reset, is the only complete American book on the subject for gas engine owners, gas engineers, and intending purchasers of gas engines. It treats fully the construction, installation, operation and maintenance of gas, gasoline, kerosene, and crude petroleum engines. It deals with the theory of gas, gasoline and oil engines as designed and manufactured in the United States, leaving out for the most part British and continenal practice, where the gas engine has received much more attention than in America. Little is known, as far as actual practice is concerned, of producer and suction gases on this continent, so that the information given by Mr. Hiscox in this work will be thoroughly appreciated. A commendable feature is the insertion of the rules and regulations of the Board of Fire Underwriters in regard to the installation and management of gasoline motors. A useful directory appears, covering the entire list of manufacturers of gas and oil engines in the United States and Canada. Besides which, is a full list of the patents issued on gas, gasoline and oil engines and their adjuncts from 1875 to date. Mr. Hiscox is to be congratulated on this volume, covering, as it does, in such a complete manner, the subject of gas, gasoline and oil engines in America.

Electrical Pocket Book and Diary. The "Practical Engineer's" Electrical Pocket Book and Diary for 1906. Manchester Technical Publishing Co., Limited. Price, 1s. 6d net.

A handsome little leather bound volume, gilt, with diary on ruled section paper, occupying about a tenth part of the whole. This book would be appreciated by all interested in electrical engineering or electrical practice of any kind. It serves as a ready reference that may be carried about without any inconvenience, being but 3 1-4 x 5 1-2 inches. The information and data pages number 440, in which are included tables, explanation of terms, formulae and descriptive matter bearing on the different branches of the art. Every electrician and engineer would find this a valuable companion.

Electrical Instruments and Testing. How to use the voltimeter, ammeter, galvinometer, potentimeter, ohmmeter, nad the Wheatstone Bridge, by Norman H. Schneider, New York, Spon & Chamberlain, 133 Liberty street, 198 pages, price $1.

In this volume the author has realized the fact that to make a treatise of this kind most effective examples of problems dealing with the subject at hand should be given. This course has been followed throughout, and adds greatly to the value of the book. The different instruments are described and dealt with in a practical manner, numerous illustrations and diagrams being used throughout, and which should commend itself to everyone having occasion to use electrical instruments, and on that account should meet with a ready reception at the hands of electrical engineers, electricians and engineering students. At the commencement the simple galvinometer is explained in an easily understood manner, after which different forms of galvinometers are dealt with, together with their practical application. The other instruments are described in turn, together with very clear diagrams of connections for making different tests. As mentioned before, the examples and problems in this book add materially to the value of it, and render it of greater practical value to those interested in electrical measuring instruments.

Reviews of the Month

OPINIONS AND STUDIES WORTH NOTING

PERPETUAL MOTION MACHINES.

IN the enlightened age in which we are living, one would almost expect that the idea of "perpetual motion" had ceased to occupy the minds of men, and that the hope of ever obtaining a machine which, once set in motion, would go forever, had been abandoned. This, however, is by no means the case, for inventors are still to be found who exercise their ingenuity in this direction. The records of the British Patent Office show that, as recently as the years 1901, 1902 and 1903, there were, respectively, 13, 10 and 9 applications for patents relating to perpetual motion. From the year 1617, the date of the earliest patent, to the present time, the subject has received a fair share of attention, the number of applications between the years 1617 and 1903 being over 600, of which only 25 have a date prior to 1855.

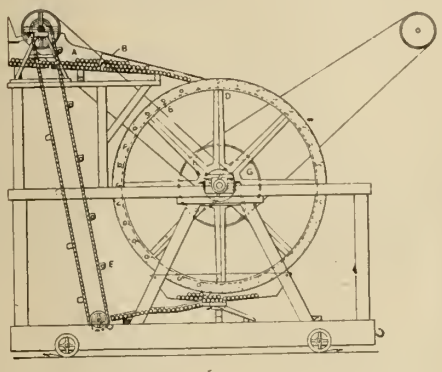


Fig. 1.

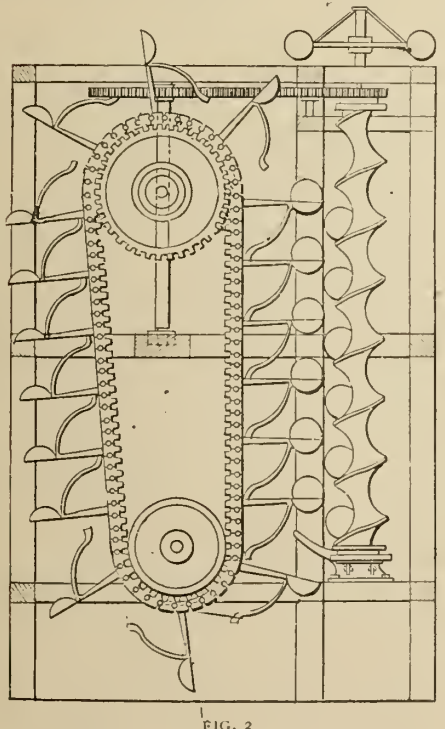

FIG. 2

In the many projects and schemes for obtaining perpetual motion, use is made chiefly of the force of gravity, loss of equilibrium, specific gravity of floats and weights immersed in water or other liquid, ascension of receptacles inflated with air or gas under water, compression and subsequent expansion of gases, and of the surface tension of liquids. That many of the inventors are perfectly sanguine of success, is demonstrated by the fact, almost humorous at times, that in many cases they provide brakes to stop their machines when necessary, or to prevent any dangerous increase of speed.

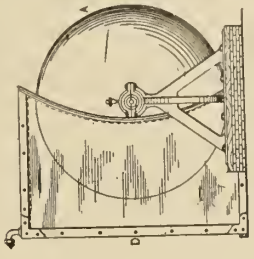

Fig. 3.

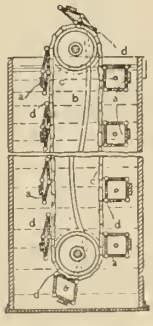

Fig. 4.

One of the commonest forms of perpetual motion machine is that in which a wheel (D), Fig 1, resembling a water-wheel, has cups or buckets on its periphery, each large enough to hold a wooden or metal ball (B). The cups on the descending side of the wheel are fed with balls from an incline (A), while those on the ascending side are empty, the difference in weight on the two sides being stated to produce rotation of the wheel. The balls roll out of the cups as they arrive at the lowest point of the wheel, and are lifted back to the incline by means of cups (E) on an endless belt driven from the wheel (D.) A pulley (G) and a belt are shown by which "motive power may be taken from the engine."

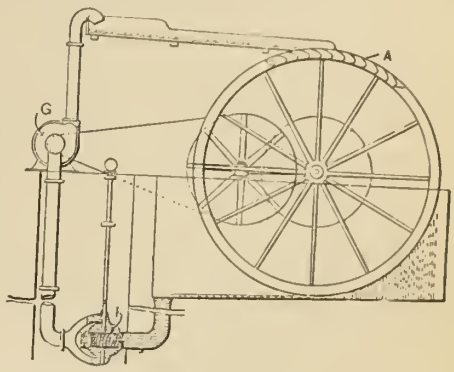

Fig. 5.

In a similar device, shown in Fig. 2, the balls fall into cups carried by an endless band. At the bottom, the balls are arrested by two horns, and are raised to the top again by a screw conveyor driven by spur gearing from the upper pulley over which the endless belt travels, a half-tube of guide rods being provided to make the balls rise vertically as the screw rotates.

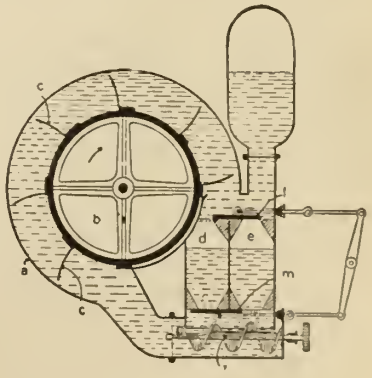

Fig. 6.

The buoyant motor, in which use is made of objects rising in liquids, has various forms. According to one, a

wheel with floats on its periphery, or a sphere or cylinder (A). Fig. 3 is mounted so that one half of it is in tank (D) of water while the other half is outside the tank, or in a vacuum chamber. The upward pressure of the water on the part immersed in it produces rotation. If there is any difficulty about a fluid-tight joint where the wheel passes from the tank to the atmosphere, the whole wheel may be immersed in the water, the buckets or floats on the ascending half being extended or made buoyant, while those on the descending half are closed. An example of this is shown in Fig. 4. The floats (a) on the endless chain (c) are made with hinged frames and are loaded so as to collapse when descending. The stops (d) prevent them from collapsing when ascending. The floats may be connected in pairs by hose pipes (b) that air may pass from one float to another.

An inventor proposes to combine the water-wheel, turbine and centrifugal

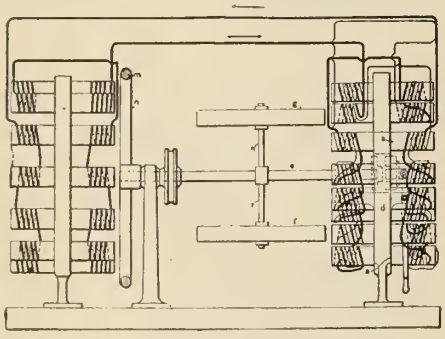

Fig. 7.

pump as shown in Fig. 5. The water, after leaving the wheel (A), drives the turbine (I), and the pump (G) is driven from the wheel (A) to raise the water again to the top of the wheel. The power is taken both from the wheel and the turbine.

An ingenious device, invented as recently as 1900, is shown in Fig 6. Here the drum (b) with folding vanes (c) is driven by water flowing alternately into the chambers (d) and (e), a vacuum being produced in the chambers by a screw (t). Valves (l) and (m), worked simultaneously open and close the chambers, one chamber being open at the top, while the other is open at the bottom, and vice versa.

The magnetic motor is another form of perpetual motion machine. A good example, invented in 1894, is shown in Fig. 7. A series of permanent magnets (a) are mounted on a fixed frame (d) so as to form two semi-circles eccentric to the shaft (e), and the like poles of the magnets face one way.

Two permanent magnets (g) are mounted on arms (h) on the shaft, their similar poles facing toward the magnets (a). The action of the magnets (a) causes the magnets (g) to rotate. The magnetization of the magnets (a) is increased by means of the windings shown, current being generated in the coils by means of an armature (n). The armature is carried by a wheel (m) on the shaft (e), which rotates in front of the magnets (i).

The motor shown in Fig. 8 should be particularly interesting to motor cyclists, for all expense in connection with petrol, electricity and other sources of power is thereby removed, the weight of the rider on the saddle places a pressure on the water on the hollow bar (D). This water passes through nozzles and drives a turbine wheel (B); it then passes to a chamber (G), from which it is pumped back to the bar (D) by pumps (H). The pumps are driven from the wheel (B) through the spur gearing shown, the vertical spindle (M) having a cam groove into which blocks on each pump rod engage. The cycle is driven by a belted connection with the turbine.

From the foregoing examples, it is evident that much ingenuity and thought have been spent upon the subject of perpetual motion, ad that in many cases it would be foolish to suppose that the inventors are cranks, on the contrary, the care and thought as to principle and detail in many of the inventions, demonstrate that many men still cling to the idea that perpetual motion is possible, and that they themselves are successfully solving the problem.— Cassier's Magazine.

OUR HERITAGE OF THE MECHANICAL ARTS.

NO certain date is attached to the most important event in the history of the mechanical arts, the discovery of iron. Iron is mentioned in the Vedas, the Upanishads, the Bible, and the Iliad; it appears in the fragments of Sanchoniathon; it is delineated upon the Egyptian monuments assigned to Thothmes III.; nevertheless the date of its discovery is a problem which is not yet satisfactorily solved. The secret of smelting iron ores and converting them into metal was certainly discovered by somebody, somewhere, and at some remote time, but we know not where, when, nor by whom. When this discovery did occur, at all events when it became publicly known and commonly put into practice, it must have exercised as profound an influence upon the ancient world as that of gunpowder and firearms has upon the modern. Iron not only armed the people who discovered it with superior offensive weapons; it enabled them to build ramparts of stone, to pierce the rocks for silver, copper, lead, and to fabricate nearly all those implements, tools and devices which distinguish the mechanical arts. The name chalybo, for iron, points to Chalybia, and of Damas, for steel, to Damas, or as we write it, Damascus. In the vicinity of both of these districts, very ancient mines have been discovered, and in the former district, at Ayazinn, Mr. Ramsay found rock sepulchres, guarded by gigantic carved lions, and a large chapel, all carved out of the solid rock, which could only have been executed with steel tools. Colonel Leake found at Nacolaeia, in the Sargarius Valley, a royal tomb in the form of a temple carved in the solid rock, with a Phrygian inscription by Attes, dedicated to Midas, while near by were the remains

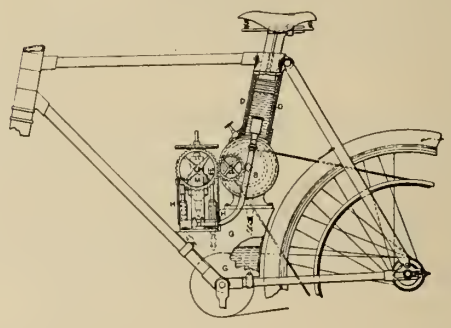

Fig. 8.

of a city, which from its great extent is supposed to have been the capital of the Sangarians, or Maryandians.

In the age assigned to the judges of Israel, about the 12th century, B.C., Jabin, the king of Canaan, or Phoenicia, who dwelt at Hazor, about 60 miles southwest of Damascus, is said to have possessed 900 chariots of iron. (Judges iv., 3) "Can one break iron from the north?" (Jer. xv., 12) and "I will break the bar of Damascus" (Amos i., 5) are passages which were probably written several centuries before our era, and may refer to a still more remote period; while they evidently point to the vicinity of Damascus as a well-known iron centre.

Could we accept these indications for a certain guide, the advent of iron, at least so far as the western world is concerned, might be fixed at about the twelfth century before our era. Both iron and steel were certainly very scarce in the west at the periods mentioned. Homer, tenth century, mentions pole-axes, shipwrights' tools, plowshares, sheep hooks, and chariot

wheels in the Troad, yet in Lacedaemonia, in the time of Lycurgus, ninth century, iron was still so valuable that he employed it as a material for money. —The Scientific American.

ELECTRIC REFRIGERATION.

EVER since the perfection of the cold storage plant, money and brains have been expended in producing an iceless refrigerator. It was generally conceded that there was a demand on the part of dairymen, soda fountain proprietors, saloon keepers, butchers, and grocerymen for something that would make them independent of the iceman, and this seems at last to have been accomplished. Besides being a great convenience, the new refrigerator has a number of other recommendations, notably its cleanliness. Because of the great amount of moisture in the interior of the refrigerator, and because of the material usually stored within, the walls tend to become foul unless cleaned with scrupulous care at frequent intervals. This condition is brought about all the more quickly where the ice is not pure. Moreover, the charging of the ice receptacle every day is a nuisance. All this is done away with by means of electric refrigeration.

The electric refrigerator is a self-contained and automatic cold storage plant in a small way. It almost takes care of itself. The switch controlling the electric current is the only part that must be manipulated.

A refrigerator of this kind has been in operation for some time as an experiment in a Philadelphia grocery store. When the store is opened in the morning, the current is turned on and remains so during the day. Although the box is being constantly opened and closed, the temperature is maintained at 34 degrees. About the best temperature obtainable by the ordinary method of icing is 40 to 42 degrees. When the store is closed for the night the current is shut off, and the temperature remains constant all night. The difference shown by the mercury between the closing and opening hours is never more than one degree. During all this time no operating expenses whatever have been incurred.

The largest soda fountain in Philadelphia has been in operation for several months, and the materials drawn therefrom have been uniformly several degrees colder than could be secured with the use of shaved ice, and yet no ice has been used in it. A motor of one-half horse-power in the cellar operates a refriegrating plant, which not only keeps the fountain at a frigid temperature, but also does some additional work of a similar character in the cellar.

The iceless refrigerator is much the same in appearance as any large refrigerator. In a compartment at one end a motor and all the necessary compressors and other paraphernalia are contained. The place usually occupied by the ice is given over to a tank containing brine, which is the means of cooling the interior of the refrigerator. The principle is identical with that of the large refrigerating establishments, but this is the first time that the system has been reduced to an automatic basis. No expert knowledge of either electricity or refrigeration is required in order to operate one of these outfits.

THE HEROISM OF INDUSTRY.

HEROES of the battlefield, and heroes of the sea! Of these, how frequently we hear — worthy often, yet often over-praised. But the heroes of peaceful industry in all the commoner walks of life—what of these? Of the farmer delving out yonder in pasture and plow-land; of the swinger of the hammer in the forge; of the builder under whose touch tower and temple spring into proud proportion? What of these world-wide common workers whose ceaseless, uncomplaining toil quickens the pulse and animates the life of nations? Who will sing their paean—who has written their history and renown?

Toil, the Creator.

We have heard among the idlers who float on the surface of society, contemptuous flings at those whose heritage is toil. They sneer at the hard and horny hand of labor; but they forget that of all that is useful, luxurious, or beautiful on earth, toil has been the creator; that from the marble mansion to the kid gloves of the tailor's most exquisite walking sign, all has been wrought out by human industry. It is the toil of swarthy hands, thou pitiful idler and sneerer—just such hands as thou see'st daily along the curb or in the crowded car—that has reared empires in the Old, and planted republics in the wilderness of the New World; that has hewn the rock in the quarry, built the "miracles in stone" that are the shrines and monuments of nations, and laid the foundations of all great modern industries; that has achieved whatever fame belongs to genius, with the sculptor's chisel, the painter's pencil, and the poet's or scholar's pen; that has winged the ocean with white sails, and exchanged the products of every clime; that has measured the circuits of the stars, and plumed the lightnings to be the swift-winged messengers of man's bidding.

Idleness a Crime.

Industry! Why, man of idleness, this is what fed you pap, rocked your cradle, and nursed your pampered life. Without it, the woven silk and wool on your back would still be in the silk worm's nest or in the fleeces of the shepherd's fold. For the meanest thing that ministers to human want, save the air of heaven, man is indebted to toil. It is only drones who toil not, infesting the hives of industry with corruption and decay. The lords of the earth—if they but knew it—are the men who do things, who can build up or cast down at will, and who can retort to the sneer of the "soft-handed" by pointing to their trophies wherever art, science, civilization and humanity are known. Work on, man of toil! Your royalty is yet to be acknowledged, as industry rises toward the highest throne of power. — Technical World.

TIME ELEMENT IN THE REPAIR SHOP.

ALTHOUGH repair shop economy has been much discussed during the last few years, there is still need of emphasizing the importance of an efficient maintenance organization in street railway shops. In some cases a narrow policy is still pursued by the management as to the purchase of improved appliances and the payment of attractive wages in the mechanical department; in others the failure to turn published experience to the best account is the result of the inability of the operating department to spare rolling stock for service long enough for thorough inspections and light repairs. Under such conditions the time required for the execution of repairs is doubly worth reducing. The key to the whole problem is good organization of labor and machinery. Motor-driven tools and high-speed steels are important factors in the repair process carried on under "forced draft" conditions, but unless the saving of time at the machine tool is to be lost elsewhere, it is necessary to investigate the repair shop problem in the same manner as do factory managers contemplating the installation of the most modern processes—processes which require one to use a stop watch and note book from the time the raw material enters the establishment until the finished product leaves the works to fully appreciate what is being done. For example, the vertical hoist is a most useful piece of machinery, but if the shop is deficient in facilities for horizontal translation, the time saved amounts to very little. Runways along which motors, axles or other loads supported by power hoists can be freely moved should be liberally provided in the repair shop, and the track lay-out in new designs ought to require the shortest possible distances of handling between departments.—The Street Railway Review.

CASE HARDENING OF STEEL.

THE process of case hardening consists in bringing the steel or iron articles into contact with carbon in closed boxes or pots and raising them to the requisite temperature for a sufficient length of time; afterward the articles are reheated and cooled by quenching in oil or water. The furnace should be so constructed as to be capable of being raised to a full orange heat (1,000 degrees C), and maintained at that heat with great regularity. Neither the fuel nor the direct flame should come in contact with the charge, that is to say, the flames should uniformly impinge on the sides and roof of the muffle, thus heating the contents of the muffle by radiated and not by direct heat. The result is most economical in the matter of fuel. There should be a small peep hole in the door, with a cover plate; a hole 1½ inches in diameter is quite large enough.

Fig. 1 shows a small furnace costing about $175. There is an upper chamber in this furnace, and though this is not necessary for case hardening it may in a small works be found useful to have such a chamber and employ it, while case hardening is being done, for the insertion of any articles which require annealing. This will add only very slightly to the amount of fuel used. Generally speaking, coal is the fuel employed; but for large works, where a large number of furnaces are kept going, gas-fired furnaces should give every satisfaction. Hardening pots are made in both cast cast and wrought iron. The latter bear re-heating so many times that they are cheaper in the end. The pots should not be of too large dimensions, or there is great risk of articles in the middle of a charge not being cased to a sufficient depth. The pots should each have a plate lid fitting closely inside.

Perhaps in no part of the process have there been so many differences of method as in the question of the carbonizing material. The carbonizers in general use at the present day are animal charcoal, bones, and one or two other compositions sold under different names, and consisting of mixtures of carbonaceous matter and certain cyanides or nitrates. For very slight hardening cyanides alone are still found very useful, but no great depth of casing is ever attempted with these.

Details of the Process.

The carbonizer having been thoroughly dried and reduced to a fine powder, a layer of not less than 1½ inches in depth is placed in the hardening pot and well pressed down. Upon this are placed the articles to be hardened. Care must be taken to leave sufficient space all round each piece to prevent its touching the others or the walls of the pot. A space of 1½ inches should be sufficient. Another layer of carbonizer is then put in and well pressed down, taking care not to displace any of the articles already packed, continuing until the pot is nearly full, and then finishing off with another layer of 1½ inches at the top. The object in view must be to make the contents of the pot as compact as possible, consistent with a sufficiency of carbonizer in contact with the articles. The more solidly a pot is packed the more effectual is the exclusion of air. The lid is then put on and the joint all round well luted with clay. By the time the proper number of pots have been filled the furnace must have been raised steadily to the full working heat. According to my experience the proper heat for case hardening is 1,000 degrees C., or a full orange "heat color."

At the close of the carbonizing period the pot is withdrawn from the furnace and placed in a dry place, where it is allowed to become quite cold. It is then opened and the articles taken out and brushed over to remove all adhering matter. If the pot has been properly packed and luted up the articles should be quite white, or, at least, have only a slight film or bloom of a deep blue color, the denser and more inclined to redness is the surface the more perfect has been the packing and sealing of the pot.

The case hardened articles are now placed in a muffle furnace and steadily raised to a good cherry red (800 degrees C.), and then quenched in cold or tepid water or oil, according to the purpose of the articles required. They should remain in the cooling liquid until they are quite cold right through the body of the metal, thus completing the process.

Then we have to determine at what temperature we are to work the cementation part of the process, and to decide this there are several points to be strictly observed. (1.) The carbon in the case must be about 0.80 per cent. (2.) The case must neither be too high nor too thin. (3.) The temperature must not be so high as to overheat the mild centre. (4.) The core must be of the greatest possible strength.

Although I have given separate requirements, we must consider them altogether. A temperature of 1,000 degrees C., if continued to saturation, would yield a carbon percentage of about 2.5; but if interrupted at any stage short of saturation the skin would contain less carbon, and the centre still less, on account of the process of diffusion being still in progress. If we take two pieces of ⅝ inch diameter round mild steel and heat one of them with a carbonizer at a cherry red heat and the other at a bright orange heat for six hours; the first will be cased to a depth of about 1-32 inch and the other to a depth of nearly 1-16 inch, while the amount of carbon taken up will be about 0.50 and 0.80 per cent., respectively. So that, so far as regards the hardness of the skin, the piece cased at the higher temperature gives the best result. From this we learn that a temperature of 1,000 degrees C. will give us sufficient hardness of case.

We have next to find which temperature has the least hurtful effect on the mild steel core. Suppose, for example, we take three pieces, heating at 1,000, 1,300 and 1,500 degrees C., or full orange, white and bright white, respectively. We shall find that those at 1,000 and 1,500 degrees break very short and have lost nearly all their original tenacity, while that at 1,000 degrees appears tougher and altogether stronger than before.—Iron Age.

THE NATURE OF LIGHNING.

THE three institute papers on lightning protection, on which we comment below, serve to point the moral which we have drawn at divers times regarding the need of knowing more about lightning prior to trying to avert it upon scientific principles. It is clear enough from the papers that the lightning under consideration was a very variable thing, and that ways and means of circumventing it must likewise be variable. For example, the excellent results from horn arresters on the Shawinigan Falls line show clearly that under the circumstances found there the minor disturbances often grouped as static, cut little figure from the operative standpoint, and that the important thing was real lightning actually striking the system. On the other hand, Mr. Torchio's description of the precautions on station lines showed plainly a system of protection directed mainly against static and induced discharges. In order to attack the problem of lightning protection with some chance of success the nature of the phenomena needs to be studied exhaustively. We know in an approximate way that lightning is of the general nature of a condenser discharge between cloud and earth or between cloud and cloud. For a long time this by a false analogy led to the conclusion that lightning is, therefore, essentially a high frequency oscillatory discharge. But it is clear that the nature of the actual discharge depends on the amount of capacity concerned and on the resistance and reactance of the path. It is easy to see that these factors may assume values leading to so great damping that the discharge would be nearly or quite non-oscillatory, and even if it were oscillatory the capacity involved would probably correspond to very low frequency.—Electrical World and Engineer.

Construction and Improvement

General Construction *Contractors' Supplies*

THE GROWTH OF SKY-SCRAPERS.

CONSIDERABLE discussion has been aroused from time to time as to the possible limit in height of the modern sky-scraper. It is now proposed in New York to erect an office building 560 feet high, which is higher than the Washington monument in the nation's capital.

As yet Canada has had little experience with sky-scrapers. At the present time there is under construction on Yonge street, Toronto, a building by the Traders Bank that when completed will be the tallest in the British Empire. It is to be fifteen stories high, and will have room for 1,500 people. The elevators will have a run of 187 feet, the flag pole being 200 feet from the ground. At the present time a storey a week of structural steel is being erected at which 100 men are engaged. The steel used in this building will amount to 1,700 tons. As the steel is erected the concrete flooring is put in. Ten thousand barrels of Canadian cement will be used in the structure, and 2,000,000 bricks. The exterior will be of grey limestone similar to that of the Flat Iron building in New York. It is fireproof throughout, the only wood being the window sashes and frames. It is expected to have the masonry completed by Spring and the building ready to occupy on Dominion Day. Steam vacuum heating and ventilation system is being installed and the entire building wired for electric light.

First Concrete Sky-Scraper.

The first sky-scraper to be constructed of cement with cement walls has been completed in Cincinnati. An illustration is shown herewith of this building, which occupies an unique position in cement walled structure. It is of the same number of storeys as the Traders Bank building, of Toronto, and bears considerable resemblance to the latter, but the Toronto building presents a somewhat more handsome appearance.

ARTIFICIAL BRICK.

Recently a large factory has been established in British Columbia for the manufacture of artificial sandstone bricks for building purposes. It is a recent German invention, in which sand and quicklime are mixed together in certain proportions, the latter hydrated in a mold in which a vacdum is produced, and as there is no space for expansion of the lime of hydration, the compression of the material follows. The brick is further compressed in stamps of high pressure and than passed into steam boilers in which a current of steam is chemical combination of the sand and kept up for 8 or 10 hours, causing a lime and producing hydrosilicate of lime. The lime acts as a binding material or cement, uniting the particles of sand together and producing a brick of exceeding hardness and practically impervious to moisture.

The Patent Roofing Co., of Brantford, in which considerable local capital is interested, will seek incorporation and establish a factory in that city.

CEMENT IN BUILDINGS.

DEVELOPMENT and expansion in the cement industry during the last decade have been phenomenal. The reason is that the product is immeasurably cheaper than stone, brick, wood, etc., their equal for most purposes and superior for many. The uses to which it can advantageously be applied are almost beyond conception, so that its growth during the next decade will undoubtedly be more wonderful than that of the last. Within the last few years the process of manufacture has so much improved as to reduce the cost more than 100 per cent.

Portland cement is made from natural rock, known technically as Trenton limestone, and when produced in commercial form is a fine powder, possessing the quality, when moistened with water, of binding itself and substances with which it may be mixed into a homogeneous mass, settling with remarkable quickness and drawing to a hardness greater than that of granite. In this condition it neither contracts nor expands, is impervious to water and unaffected by the most intense heat or cold.

In its commercial form the cement can be molded into any required shape. It is used "neat" and in combination with either sand, gravel, crushed stone, cinders, clinkers or slag, dependent entirely upon the uses to which it is to be applied, strength of material required or appearance desired. Many block machines have been invented, and blocks of cement stone of any size, shape or ornamentation can be cheaply and quickly manufactured. These machines make a perfect imitation of stone in any desired color or form, and can be colored in imitation of brown stone, red stone or of a greenish or bluish tinge, making a building more ornamental than can be produced by any natural rock.

Portland cement with iron or steel is used with great economy in the construction of skyscraper buildings, and will doubtless be so used to the almost exclusion of stone and brick in the near future. Scarcely a modern building is now constructed or can be constructed without the use of cement. As was demonstrated in the great Baltimore fire, cement or steel and cement in combination, provide the only fireproof building material.

A New Method of Worm Wheel Cutting

By W. B. McLean, B.Sc.

WHILE worm gearing has been in use to some extent in the manufacture of machinery for a very long time, such rapid advances have been made in the methods of manufacturing it of late that it is practically a new business and the amount of worm

RETURNED
JAN 15 1906

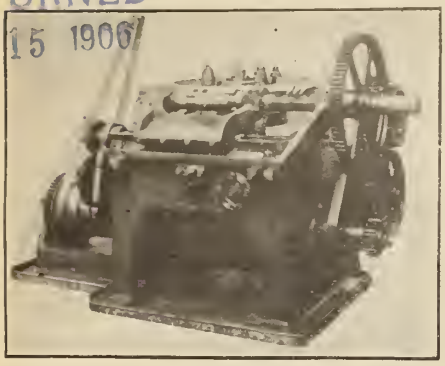

Fig. 1.

gearing which is in use has increased within the last eight or ten years by something like 300 to 400 per cent. and is still growing very rapidly.

The old fashion in making worm gearing was to cut the worm in a lathe and to cast the teeth in the worm wheel. Various methods, more or less intricate, are described in text books for designing the shape of the teeth, and no doubt if the best of them were worked out fully and carefully followed by the pattern maker and moulder we should get a tooth of approximately the correct shape and get a line contact right across the tooth for each thread of the worm in gear. These shapes are so difficult to draw, however, and so much more difficult to make when they are drawn, that in practice shapes of teeth in cast wheels are very far from correct and the thread of the worm only touches the tooth in one or two places.

Usually the thread of the worm will not go into the tooth space at all and then the tooth space has to be chipped with hammer and chisel to get a bit nearer and finally the worm is case hardened and left to grind the wheel down to the proper shape. It is no wonder in view of all these circumstances that there has been a very strong prejudice against the use of worm gearing and that it has been of very low efficiency.

As far back as 50 years ago Sir Joseph Whitworth devised a method of cutting worm wheels by means of either a single cutter or a hob. In his machine the wheel blank was revolved and the cutter or hob fed in directly towards the centre of the wheel. This, however, did not give a perfect form of tooth.

The modern method which has been in use for about ten years only is to set the axis of the hob or single cutter at the same distance from the centre of the wheel blank which the axis of the worm is to have in the finished wheel. The hob or cutter is fed from one side of the blank tangentially across it, emerging at the other side. The movement is equivalent to that of a worm driving a finished wheel and at the same time threading its way through it along its axis from one side of the wheel to the other. It will be seen that this method is bound to give a shape of tooth to fit the worm in every part, as, in fact, it is equivalent to the worm cutting its own wheel.

In the case of a machine of this description which has a constant feed by gearing or otherwise, that is to say, having the cutter moving tangentially through equal distances for each revolution of the worm wheel being cut, the revolutions of the cutter are in a compound ratio to the revolutions of the wheel being cut. This will be seen by considering two extreme cases: If the tangential feed were nil it will be seen that the case is exactly like that of a worm, of which the cutter is an equivalent, driving the wheel being cut, and the ratia of the revolutions would simply be that of the finished worm when

RETURNED

Montreal
Cut Book 45
page

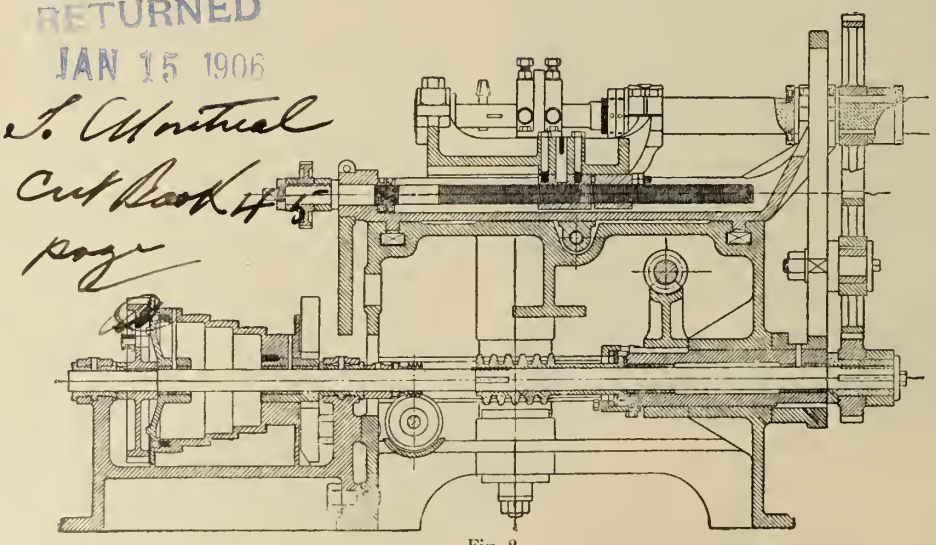

Fig. 2.

driving the finished wheel; if, on the other hand, the wheel being cut were not revolved at all but held steadily, and the cutter fed directly across it, then it would be like the finished worm threading its way through a fixed nut and the revolutions of the cutter would simply be the feed in inches per minute divided by the lead of the worm in inches..

We must here differentiate between lead and pitch. Worms are very often not single threaded like an ordinary screw, but double, treble and multiple threaded, as many as 11 or 12 thread worms are sometimes used. The term "pitch" is usually used to denote the distance between corresponding points of one thread and the next; the "lead" is the distance which a nut on the thread would move along the axis in one revolution.

In the case of actual worm gear cutting both of the above mentioned motions are going on at once and the resulting ratio which must be maintained between the cutter and the wheel being cut is compounded of both of them. To take a concrete case, suppose we are cutting a worm wheel of ratio 40 to 1 at 1-in. lead and the feed is 1-16-in. per revolution of the worm wheel, the ratio of the revolution of the cutter to that of the wheel being cut must then be $40 \pm \frac{1}{16}$. If the lead were 2″ the ratio would be $40 \pm \frac{1}{32}$, and so on.

In general, if the ratio of the worm of the finished wheel is called "r" and the feed in inches per revolution of the wheel be called "f" and the lead of the worm in inches be called "l," then the ratio of the cutter bar to the wheel must be

$$r \pm \frac{f}{l}$$

In all the earlier machines for cutting

worm wheels on this principle complicated arrangements involving the use of at least three trains of gearing were used for producing this ratio. The feed was produced simply enough by a set of change gears connecting with the wheel being cut and driving a lead screw which fed the cutter along its axis. The cutter bar was geared up by change wheels to the wheel being cut in the simple ratio of the worm of the finished wheel, then a complicated arrangement—usually a nest of bevels, or "jack in the box," as it is sometimes called—was resorted to for adding or subtracting from the revolutions of the cutter by an amount proportionate to the tangential feed of the cutter, that is to say, the two elements of the compound ratio were produced separately.

RETURNED
JAN 15 1906

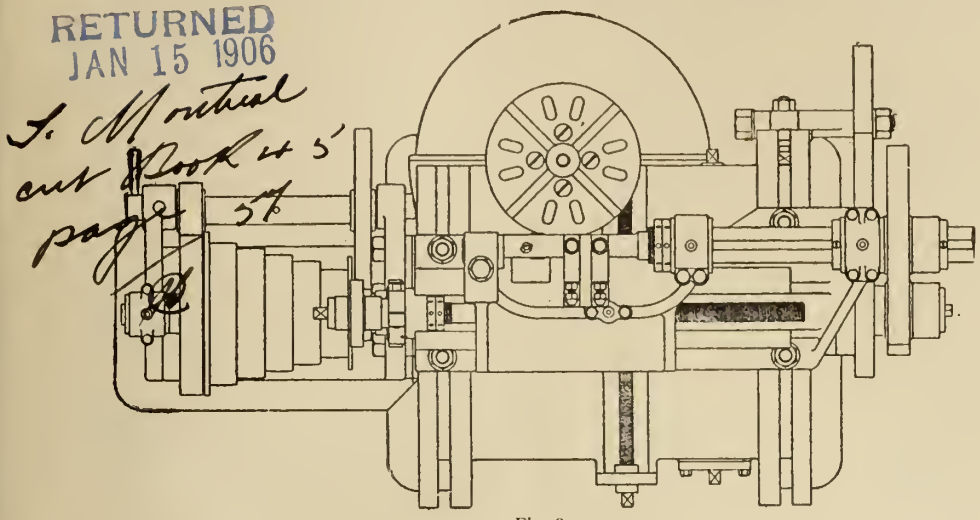

Fig. 3.

One advantage of this method over that which we are about to describe is that the feed may be varied across the face of the wheel, that is, it may be made faster as the cutter is just entering and leaving the wheel and slower at the centre. The great disadvantage is that it involves very complicated and expensive machinery.

In the machine designed by the writer only two trains of gearing are used; one is for feeding the cutter along its axis and may be seen on the left of Figure 1, the other is for connecting the wheel being cut to the cutter bar and may be seen on the right of Figure 1. This makes the simplest possible machine. It might be thought, however, that the compound ratio necessary for the gears driving the cutter bar would be so complicated that it could not be produced with any ordinary sort of gears. It will be seen, however, in the formula found above, viz., the ratio of gear required which we will call

$$g = r \pm \frac{t}{1}$$

that there are two quantities which may be varied, viz., that "g" is dependent on the feed "f" as well as on "r." It is not essential in practice that the feed "f" be exact; it may be varied slightly, say within 10 per cent. of the value which is required, that is to say, in a concrete case we want a feed of about 1-16; 1-15 or 1-17 would do as well. We can always find by a little calculation the value of the feed "f" which will give a ratio "g" which can be obtained with an ordinary assortment of change gears.

In proceeding to consider a concrete case of this we must observe the significance of the plus or minus sign in the formula. The cutter for several reasons must always cut on its down stroke, that is, so that it will not tend to lift the wheel off the face plate. In Figure 5 let the circle denote the worm wheel with the curved arrow showing the direction of rotation and the outside arrow the axis of the cutter or worm. It will be seen that the case shown is that of a right hand wheel. If the feed of the worm is in the direction shown by the outside arrow then the added motion due to the second element in the compound ratio is in a different direction to the motion due to the first element, that is to say, if the worm were going to thread its way through the wheel it would be moving in the opposite direction to that which it would be for driving the wheel as indicated, hence the minus sign must be used in the formula.

By similar reasoning it will be seen that the minus sign must also be used in the case shown in Figure 6, which is that of a left hand wheel, and in general the minus sign must be used when the direction of the feed is such as to follow the motion of the periphery of the wheel, and conversely the plus sign must be used when the direction of the feed is the opposite. It is found in actual cutting that it is best to feed with the periphery of the wheel and hence the minus sign is used in the formula.

As an example of the method of working out the gearing let us take the case of the 40 to 1 wheel with 1-in. lead of worm as mentioned above, the feed to be about

$\frac{1}{16}$. By the formula

$$G = 40 - \frac{1}{16} = \frac{639}{16} = \frac{9 \times 71}{16}$$

but 71 is an odd gear not likely to be

RETURNED
JAN 15 1906

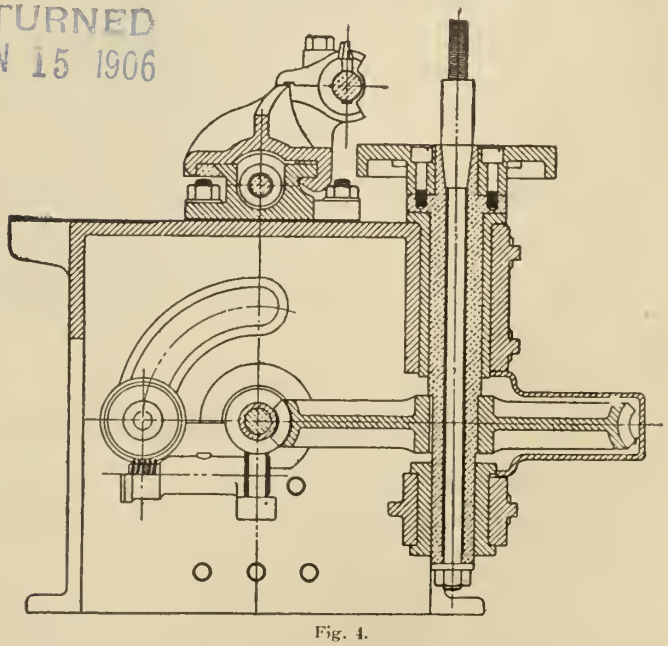

Fig. 4.

in stock. To get a better ratio proceed as follows:

$$40 - \frac{1}{16} = 40\left(1 - \frac{1}{640}\right) = 40 \times \frac{639}{640}$$

Refer to a table of prime factors of numbers which is used in these calculations and find two consecutive numbers

as near as possible to 640, both of whieh will factor out. Take say 637 and 638

$$40 \times \frac{637}{638} = \frac{20 \times 7 \times 7 \times 13}{11 \times 29}$$

Also working backward to the formula

$$40 \times \frac{637}{638} = 40\left(1 - \frac{1}{638}\right)$$

The feed ÷ lead is $\frac{40}{638}$.

The lead is 1-in. hence the feed to match the above gears is

$$\frac{40}{638} = \frac{20}{11 \times 19}$$

If the lead screw feeding the cutter has four threads to the inch the ratio of the feed gearing between the lead screw and the wheel being cut will be evidently

$$\frac{20}{11 \times 19 \times 4} = \frac{5}{11 \times 19}$$

In both the feed and cutter bar gearing the reduction is not all done by change gears. Part of it is done hy fixed gearing whieh is so arranged that an average case would require equal change gears.

A machine designed on these principles is manufactured by Messrs. H. Wallwork & Co., Limited, of Manchester, and has met with great success in England. Sectional drawings are shown in Figures 2 and 4, and a plan in Figure 3. The worm wheel to be cut is fastened on a horizontal faee plate as shown in plan towards the top of Figure 3 and in section at the upper right hand corner of Figure 4. This is driven by a vertical spindle shown in Figure 4, which has a worm gear attached to it. This worm gear is driven by a worm on a horizontal main driving shaft shown in the lower part of Figure 2. This driving shaft goes right through the machine and carries the driving eones and back gear as shown to the right of Figure 2 and 3, and at the other end carries the first of the change gears for driving the eutter bar as shown to the left of Figure 2. The cutter bar is earried on a carriage which slides in and out to adjust for different eentres and also trav-

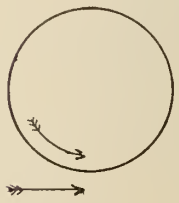

FIG 5

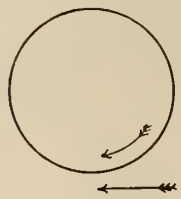

FIG 6

els across the wheel to give the tangential feed, being driven by a lead screw shown in the upper part of Figure 2 and in plan towards the centre of Figure 3. The feed gears are driven from the main driving shaft by a double worm and wheel arrangement shown towards the centre of Figure 4. The hox earrying this gear swivels on the main driving shaft and the outer spindle of it slides and may be clamped in any position in an arc shaped slot. The first of the ehange gears for driving the feed screw goes on this spindle and the movement in the slot faeilitates the gearing up. The swing frame for carrying the change gears for driving the cutter bar, which is of some weight when loaded up with the gears and would be awkward to manipulate by hand, has a special arrangement for moving it up and down shown in Figure 2. It is keyed to a sleeve which is free to move round in a hearing in the frame. The driving shaft runs through the centre of this sleeve in bearings and to the inner end of it inside the frame a worm wheel quadrant is attached and this is worked by a worm, which is supported in bearings in the frame. The ends of the spindle of this worm come out at both sides of the frame and are squared as may be seen in Figure 3. By working this spindle with a crank handle the swing frame may be moved up and down easily although heavily weighted, and may be nicely adjusted to bring the gears into proper mesh.

The machine may be used either with a single fly cutter or a hob. The fly cutter is shown in position in one of the arbors towards the top of Figure 2. These arbors, whieh fit into the end of the cutter bar hy morse taper and run in bearings, are of different sizes and may be easily removed and replaeed.

The whole machine is made very strong and with powerful drives with a view to using high speed steel cutters.

A PURPOSE.

Have a purpose in life, and having it, throw into your work such strength of mind and muscle as God has given you.

—Carlyle.

A Prayer.

The day returns and brings us the petty round of irritating concerns and duties.

Help us to play the man, help us to perform them with laughter and kind faces; let cheerfulness abound with industry.

Give us to go blithely on our business all this day, bring us to our resting beds weary and content and undishonored; and grant us in the end the gift of sleep.—Amen.

—Robert Louis Stevenson.

Power and Transmission

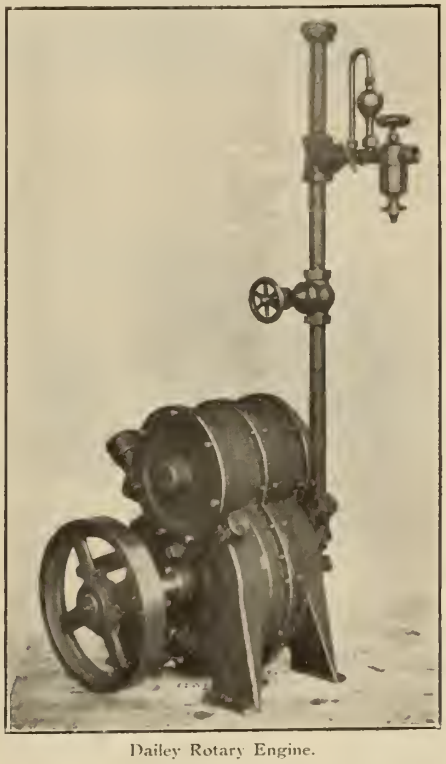
Steam Gas Electricity Compressed Air Water

OPPORTUNITY FOR GAS ENGINE BUILDERS.

PRODUCER gas at the present time is attracting considerable attention from power users. The attractive feature is the small coal consumption per horse-power that has been attained throughout England and Germany through the medium of this gas. In Canada and the United States this low coal consumption is now being demonstrated in not a few installations. England and Germany are the pioneer countries in the production of gas and gasoline engines, and there the design and mechanical construction of gas engines especially have reached a higher state of development than in any other country. Conditions peculiar to these countries is the reason for this. Naturally then, Canadian and American engineers have gone to these countries, particularly England, for data concerning gas and gasoline engines.

The most recent development along this line for comparatively small units has been the producer gas plant, consisting of the gas generator and engine especially designed for producer gas in a complete power plant. Of these producer plants the suction gas plant is receiving particular attention. Theoretically these producers are automatic in operation once the engine has been started, but the varying load on the engine in actual practice requires that even the best designed and constructed engine receive more or less regulation of air and steam supply. The efficient manner in which all otherwise waste heat units are utilized accounts for the economical generation and application of power by means of these power plants. In actual operation the gas is produced by the suction of the intake stroke of the engine drawing regulated supplies of steam and air up through a bed of incandescent coal. The steam is generated in a boiler surrounding the generator, and thus the heat units that would otherwise have been radiated are utilized and the heat units given off in the cooling of the gas to the correct temperature for use in the engine are also utilized in the heating of the water before it enters the boiler. The generation of the gas is started by means of a hand blower and after the engine has been started the operation of the plant is exceptionally simple if the load on the engine is constant. In the majority of cases, however, this is not so, and thus regulation of the air and steam supplies requires considerable attention in order that the quality of the gas may be kept as uniform as possible.

Considering the short time that the suction gas producer has been in use the economical results obtained are very creditable. Little unforeseen snags are often met with in the actual operation, and it may be some time before the producer has reached that stage of perfection that these little difficulties will no longer be met with. But this should in nowise discourage either the manufacturer or the user. It has taken many years to bring the steam plant up to its present degree of perfection. Considering the comparative efficiency of the suction gas plant with that of the steam plant as a basis for calculations, it is safe to predict a decidedly good future for the suction plant.



Dailey Rotary Engine.

At present producer gas generators for power purposes on the Canadian market are either English or American make, although several plants have been made in Canada for heating purposes. There are, however, several firms now experimenting along this line in Canada with a view to manufacturing. Some of these firms will probably make their own engines, while others will not, preferring to devote all their resources to the development of the producers. Since producer gas is so much less rich in heat units than ordinary coal gas or natural gas, that especially designed engines are necessary to get the most efficient results from producer gas, the chief feature of difference being the comparative smallness of the clearance chamber, which is to provide for the higher pressure necessary in the proper combustion of producer gas with the air.

In consequence there is a field for manufacturers of gas engines in the development, in conjunction with the firms manufacturing the producers, of a line of engines suitable for producer gas. Unless Canadian engine builders take advantage of this opportunity—which opportunity is great, viewing the producer gas plant in the light of its present achievements and future possibilities—it is probable that suitable engines will be imported from England to complete the producer gas plants made in Canada. The management of one firm, at least, has the importation of engines from England definitely in mind, unless some Canadian builder produces a reliable engine of the required type before their gas generators are ready to be placed on the market. Canadian manufacturers must take advantage of opportunities as they are presented, else manufacturers from other countries will step through the door standing open for them.

DAILEY ROTARY ENGINE.

IN the last issue an account of the remarkable engine invented by Mr. Chas. Hetherington, of Galt, was given. It was intended at the time to give an illustration of same, but the photograph arrived too late to have half-tone made. Herewith is presented a representation of same, so that readers may have as idea of the general features of the interesting little prime mover.

THE TURNER CARBURETTOR.

IN their endeavor to supply a simple and reliable carburetting device, the Turner Brass Works, Chicago, has designed two types, one for use with four-cycle automobile engines and one for two-cycle marine engines. The ae-

companying Figs. 1 and 2 show these two carburettors. They are made entirely of bronze, because iron has a tendency to corrode, interfering with the prompt action of the moving parts. The carburettor is of simple construction and is claimed to give a perfect mixture at all speeds and under all atmospheric conditions. It is described as a simple poppet valve carburettor and has as a distinguishing feature an individual constant vacuum system of control. The latter is said to overcome all such difficulties as irregularities of the mixtures at different speeds of the motor and imperfect vaporization of the fuel for starting in cold weather, and to dispense with the necessity of priming, heating or using high grade gasoline. In fact, the carburettor is not well adapted to gasoline of higher grade than 68 or 70 degrees. In cases of emergency wood alcohol may be used, and the motor will start with this fuel exactly the same as with gasoline.

Fig 3 shows two sectional views of the auto type carburettor which indicate the principle of its operation. The poppet valve E performs the function of the float as used in the regular feed type of carburettor for shutting off the flow of gasoline and takes the place of the throttle and auxiliary valves used in other carburettors. In other words, this one valve performs the functions of feeding, vaporizing and controlling the mixture and the quantity of it to be delivered to the motor. The valve also affords a cut off for the gasoline supply, which is not affected by vibration when in operation and is a positive and automatic cut off when the motor is stopped.

The poppet valve E is normally held to the seat S by the light coil spring G and auxiliary spring N, completely closing the air passage through the carburettor. It also seats on the end of the gasoline supply tube L-I, thereby preventing the flow of fuel except when drawn in by the suction of the motor. When it is desired to admit a full charge

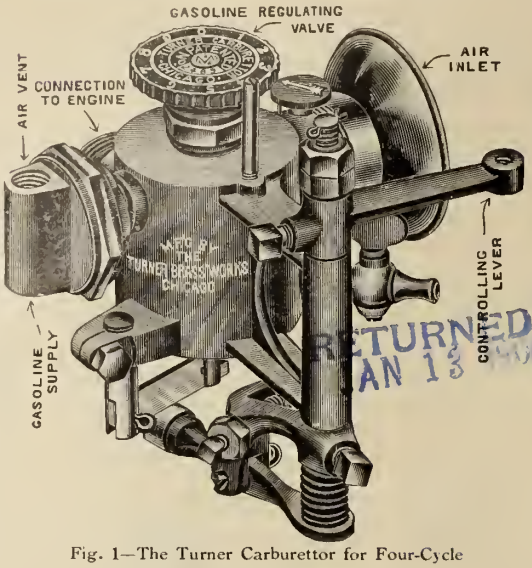


Fig. 1—The Turner Carburettor for Four-Cycle Auto Engines.

of air and gasoline, tension on the auxiliary spring N is removed, leaving only the tension on the light coil spring G

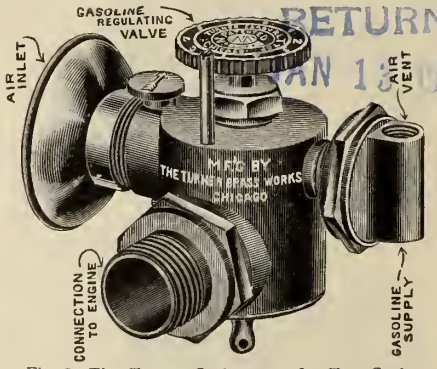

Fig. 2—The Turner Carburettor for Two-Cycle Marine Engines.

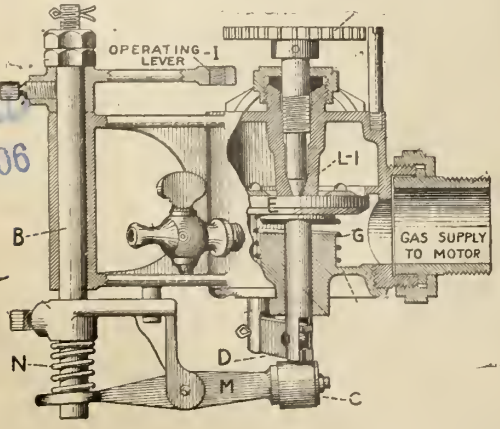
to be overbalanced by the engine suction. Under these conditions the valve will remain open during the full suction stroke of the piston. To decrease the charge admitted the tension of the auxiliary spring N is brought into action by turning the operating lever I; this acting through the rod B causes the lever M, through the roller C, to press with increased effect on the link D, which assists in holding the valve E closed. As a result a greater vacuum is formed before the valve opens to admit gas to the motor. In creating this vacuum a part of the stroke of the piston is spent, leaving only the remaining part to draw in the charge. The gasoline flow can be thus controlled in exact relation to the air supply and the vaporizing power increased as the size of the charge is reduced, making a positive feed of fuel certain regardless of the quantity.

One of the most valuable features of the Turner carburettor is that no change in the air or gasoline adjustments is necessary to maintain an absolutely even mixture between a full charge at any speed or the smallest charge that the motor will fire at the slowest speed. In starting the motor the poppet valve also affords a positive feed of exactly the right amount of fuel, and, due to the high vaporizing power, the motor will respond immediately to the first charge drawn through the carburettor.

B. C. MEN INVENT.

ACCORDING to a Vancouver paper two men of that city, a machinist and a locomotive engineer, have been granted a patent on an improved lock handle for stop-cocks.

This handle has been particularly designed for application to what is known as the angle cock, at each end of a vehicle, on the Westinghouse air brake train pipe, to prevent such stop-cocks being inadvertently closed. This unintentional closing of an angle cock, by cutting off the rear portion of a train from connection with the air brake



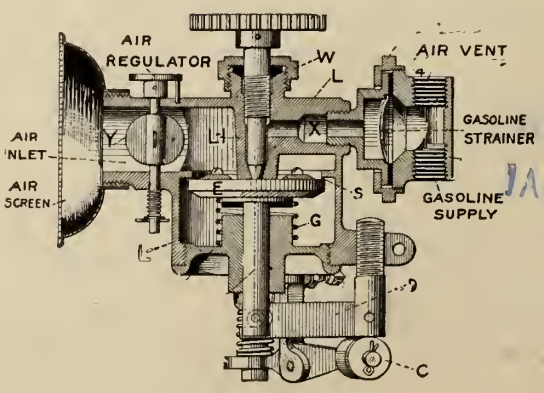


Fig. 3—Two Sectional Views of the Auto Type of Carburettor.

system, has been the frequent cause of railway accidents, which hitherto could hardly be considered as preventable. This handle, which is the subject of this patent, is provided with a detent which locks it in either the open or shut position as required, so that it cannot be accidentally moved.

The invention is a very ingenious and eminently practical one, and should be readily adopted by the various railway companies, as no modification of the body of the stop-cock is required, the old handle merely requiring to be removed and the new one substituted at a comparatively trifling expense, while it will save the recurrence of a class of accidents which are usually disastrous to rolling stock; and the cause of serious interruption of traffic.

The air brake companies will also be too willing to adopt an invention which will enhance the usefulness of their brake system.

A NOVEL WATER HOIST.

THE question of unwatering a mine always is a serious problem to the mine management, especially so when the water is highly impregnated with acids. When the amount becomes excessive the means to be employed for disposing of it taxes the ingenuity of all concerned to the uttermost.

In the anthracite regions there are mines in which for every ton of coal raised, as high as 14 tons of water must be pumped and the latter must be done at a minimum of expense. Nowhere, probably, have a greater variety of pumps and lifting devices been tried, and the most satisfactory type, up to date, for handling large quantities of water at comparatively low heads, have proved to be large boilers operated by steam engines. These, however, lack the mechanical regularity inherent in a pump, as they are necessarily operated by men, and it remained for the Delaware, Lackawanna & Western R. R. Co. and its electrical engineer, Mr. H. M. Warren, to finally develop a water-hoisting equipment which would preserve all the valuable points of the steam hoist and at the same time operate automatically. The carrying out of the mechanical details of the hoist and its automatic devices were confided to the Wellman-Seaver-Morgan Co., of Cleveland, Ohio, and the successful operation of the plant reflects great credit on the latter, as they guaranteed the machinery to accomplish the desired results. Most of the electrical controlling devices were furnished by the Electric Controller & Supply Co., of Cleveland, Ohio. In the original specifications the D. L. & W. R. R. Co., called for the hoist to be operated by an alternating current motor of 800 H. P. and the question of starting, stopping and reversing so large a motor had at the outset, to be met. The duty to be performed by the hoist called for the raising of 4,000 gallons of water per minute to a height of 550 feet.

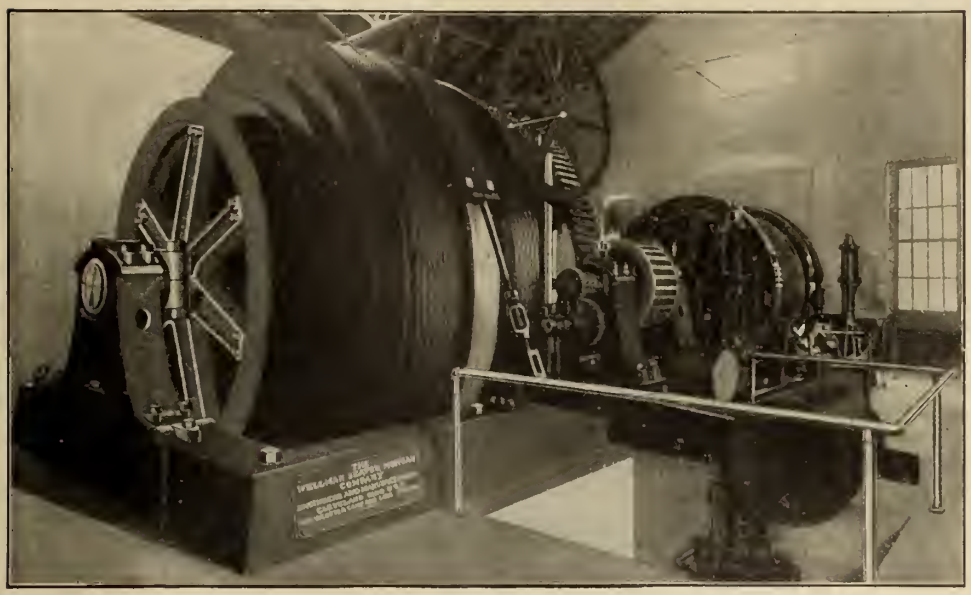

Fig. 1

4000 gals. × 8.27 = 33180 lbs.

550′ 2″ rope × 6.3 = 3465

36645 lbs. to be raised at 550′ per min.

$$\frac{36645 \times 550}{33000} = 610 \text{ net horse power.}$$

Weight of bucket = ½ weigh of water, so that weight on rope = 53,235 lbs. or nearly 27 tons, requiring 2″ steel rope.

It was decided in carrying out the design that it would be impracticable to design the hoist other than have a motor running continuously in one direction, as it is a well known fact that the amount of current required to accelerate a large motor of this type is enormous, and greatly interferes with the proper running of the power plant.

The D. L. & W. R. R. Co. desired to use an A. C. motor directly at the hoist, and as the motor was to run continuously in one direction, this necessitated the use of friction clutches for accelerating and reversing the load.

As the Wellman-Seaver-Morgan Co. had several smaller plants already in operation using A. C. motors on hoists which are operated similarly to the present hoist, and as they are running successfully, and the repairs and renewals for clutches had not exceeded that required for the other hoisting engines, it was decided to use this method.

Figs. 1 and 2 show a front and side view of the hoist. As will be noticed, the general arrangement consists of a motor driving a pair of bevel wheels through a single bevel pinion. The bevel wheels run loose on a shaft and are fitted with the well known Webster, Camp

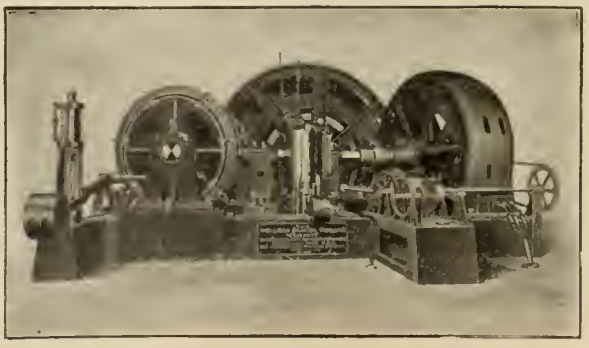

Fig. 2

& Lane friction clutches. The operating mechanism for the clutches are so designed that only one clutch can be thrown in at a time, but both clutches can be out at the same time. Throwing in one clutch runs the drum in one direction; throwing in the other clutch reverses the motion of the drum.

To the shaft on which the bevel wheels run there is keyed a pinion meshing with main gear on the drum shaft. The drums are of the cylindro-conical type 10 feet at the small diameter and 16 feet at the large diameter. At a hoisting speed of 550 feet per minute the drum makes about 15 R P.M. There is one main brake located between the drums. All of the clutches and brakes are operated by auxiliary air cylinders fitted with oil cushion cylinders, the compressed air being furnished by a motor driven air compressor and the necessary tanks located near to the hoist. The hoist is controlled by a mechanical device shown in Fig 2. This device consists mainly of a drum rotated by means of a friction drive from the motor through a sprocket chain. The drum shaft transmits its motion to a secondary shaft fitted with variable speed which in turn operates a secondary stop. The main hoisting drum shaft operates a traveling nut which is so located with respect to the controller drum that at either end of its travel it releases a stop and allows the controller drum to make a quarter turn; this movement, through suitable electrical connections, operates the solenoids on the clutch valve, releasing the clutch and the solenoid on the brake valve setting the brake, the further movement of the controlling drum being arrested by the secondary stop. This stop is released by the variable speed shaft and its connections, which has been given a predetermined time movement corresponding to the interval for emptying the bucket The further movement of the controlling drum releases the brake and throws in the reversing clutch, thus starting the hoist in the opposite direction, and also starting the traveling nut on the controlling mechanism in the opposite direction. At the end of the hoist the cycle of controlling movement is repeated and so on, making the hoisting operation continuous and automatic. Every attention has been given to the safe operation of the hoist. The main brake is of the gravity type and to be released the current must be on the solenoid operating the valve so that air can be admitted to the underside of the brake piston. If for any reason, either the supply of current or of air pressure is interrupted, the valve drops, and the weights on brake lever set the brake. The clutches are designed so that they are thrown out by weights. As is the case with the brake, either clutch can only be thrown in when the current is on the solenoid, and the air pressure admitted under the piston, and if either current or pressure fail, the clutch is off. The motor shaft is fitted with an emergency brake operated by a weight controlled by a solenoid—any interruption in the flow of current to the motor sets the brake and stops the motor. Any interruption of the flow of the current stops the machine, throws out the clutches and puts on the brake. A safety cut-out is provided for in the head frame so that in case a bucket is carried beyond the proper height, the current is cut off. Fig. 3 shows the head frame. The head frame is 93 feet from the base to the centre of the sheave at the top. It is built of structural steel, roughly in the shape of an "A." From the head frame are suspended two buckets 6 feet in diameter and 19 feet 6 inches deep. The capacity of each bucket is 17 tons of water. In the bottom of the bucket are located two lift gates with an area practically equal to the cross section of the bucket.

These gates are lifted automatically when the bucket reaches the top, and the water is discharged through the bottom into a spout fitted below the bucket, and which deflects it to either side of the shaft. Each bucket makes a complete round-trip in one minute and fifty seconds, the total lift being 555 feet.

Chicago Hose Coupler.

Fig. 3

THE CHICAGO HOSE COUPLER.

THE Chicago hose coupler was designed to meet the demand for a universal coupler whereby a plant once standardized could economically thereafter be maintained standard without extra expense for specially con-

structed couplers to suit various sizes of hose used with pneumatic tools.

As to how perfectly the manufacturers have succeeded, we will leave the subject to the opinion of those requiring such equipment, after a test of the device in question.

By reference to the illustration it will be observed the Chicago coupler has no male or female part at coupling end proper, but instead, each half has embodied therein both male and female features, whereby each and every half is exactly the same and will couple regardless of the size and style of the shank, rendering the same an universal coupler in every sense of the word. It will readily be seen that quarter inch hose may be coupled with three-quarter inch hose, one inch pipe, or to anything having one of the Chicago couplers attached to it.

The shanks are manufactured for pipe male thread, pipe female thread, and hose in standard commercial sizes one-quarter inch up to one inch, which enables all couplings to be made without resorting to reducers or special shanks to meet the conditions presenting themselves where pneumatic tools are in use.

These couplers are manufactured by the Chicago Pneumatic Tool Co., who have arranged to carry a large stock constantly on hand which they are enabled to do from the fact that their manufacturing facilities are equal to 500 sets per day.

Improved Ventilator Fan.

BLAST FURNACE GAS.

PROPER precautions regarding blast furnace gas and its possible effect on the workmen engaged in the blast furnace is often not considered, or, if considered, not acted upon as the occasion demands. Safety to workmen and protection of human life should be the foremost consideration in every industry and yet too often accidents occur that with slight attention and proper foresight could well have been avoided. In a paper read before the Iron and Steel Institute some good suggestions regarding avoiding accidents due to blast furnace gas were brought out. It was intimated that where practicable all gas flues and gas pipes should be placed above the ground and if possible above the breathing level, and that when the gas flues are under ground they should be built of blue bricks set in cement, while the man-holes leading to these should be equipped with lids ensuring the maintainence of perfect gas tightness. All habitable buildings should be thoroughly well ventilated. The ground surface below the building should be covered with a layer of cement concrete, and an open air space should be formed between the cement surface and the flooring boards of the building. Forced ventilation should be the principle adopted for all occupied buildings in iron and steel works. An air-supply tapped from the cold blast main may be found useful in this connection. The gas engine exhaust pipes should terminate at a considerable altitude above the works air tube of the blowing engine should be supplied from the engine house. Especial precautions should be taken during flue and stove cleaning periods, and in blowing in furnaces. Enamel lettered warning notices should be prominently posted throughout the works. Fines should be imposed on workmen for gas risks carelessly undertaken. A paid ambulance corps should be established. During the blowout period of the slag tapping operations the men should be withdrawn from the zone of gas escape. The time allowed to be occupied in gas producer poking operations for individual men should be limited to three minutes. The reversing valve pits of gas-fired furnaces should be well ventilated. Roll call checks of labor employed in gas flue and stove cleaning operations should be established. If power gas pipes have to be placed underground, they should be placed in grate covered open trenches, and the pipe flanges should be planed.

Following out all the suggestions mentioned would mean some added expense and, for a time at least, considerable attention, but the matter is worth thoughtful consideration by all interested.

IMPROVED PROPELLER FAN.

IN the illustration shown in this page an idea of the improved propeller fan recently placed on the market by the McEachren Heating & Ventilating Co., of Galt, is given. This fan is of new and improved design. It is not at all like the ordinary disc fan, nor like former patent disc fans. As will be seen by the illustration, the wheel has no band around it. The whole wheel stands out in the space from which the air, steam, gas, etc., is to be taken.

What is peculiar about this fan is that it takes in air all over the face of the wheel and all around the periphery, and discharges it nearly all over the surface of the opposite side of the wheel but mostly at the centre.

If this fan has to be inserted, or partly inserted, into a wall or tube, it is necessary to have the space around the periphery of the wheel not less than from 12 in. to 24 in. larger in diameter than the diameter of the wheel.

These fans are light; they are adapted for placing in windows or hanging to ceilings. Although of light weight, they are strong, the castings being all angles and tees, which is the strongest form in which a given weight of metal can be employed.

The fan illustrated is adapted for fastening to a wall or partition, but fans are supplied with feet to stand on a floor or platform, or to run on a vertical shaft in steel step if required, and with but small extra charge.

The Dominion Iron & Steel Company will add two Bessemer converters to their plant so as to increase their steel output sufficiently to meet demand for rails. This means an increase of 35 to 50 per cent. in the company's present output of steel, and it is expected the monthly output will be 20,000 tons next year.

ABOUT CATALOGUES

By mentioning Canadian Machinery, to show that you are in the trade, a copy of any of these catalogues will be sent by the firm whose address is given.

Sturtevant Enginnering Series. The B. F. Sturtevant Co., Boston, Mass., will hereafter issue most of its publications periodically under the title, Sturtevant Engineering Series. Tach individual bulletin will treat of some particular product or its application. The series will also include reprints of pertinent articles or technical papers. All publications will be issued in uniform style and size suitable for binding consecutively or in allied groups. Bulletin No. 125, the first of this series, has just been published. It describes in detail the line of automatic vertical engines manufactured by the B. F. Sturtevant Co. These range from 5 x 5 inches to 12 x 10 inches, are entirely enclosed and all bearings are provided with positive forced lubrication under 15 pounds pressure. hese engines primarily designed to meet the exacting requirements of dynamo driving, are capable of continuous operation without skilled attention and represent the highest standard of material, workmanship and efficiency.

Pneumatic Appliances for foundry and concrete block work. Special Circular No. 55, issued by Chicago Pneumatic Tool Co., Fisher Building, Chicago. Besides describing pneumatic appliances, this booklet gives some good information on coloring concrete and its preparation. Twenty-four pages, 6x6 inches.

Slab Milling Machines. The Newton Machine Tool Works, Philadelphia. are sending out their Catalogue No. 42, devoted chiefly to a description of their horizontal slab milling machines. Other lines manufactured by this firm are also described and illustrated. 24 pages, 6 x 6 inches.

Lubricating Graphite. The United States Graphite Co., Saginaw, Mich., are sending out to engineers and others particularly interested in lubrication, a sample of their graphite accompanied by an interesting pamphlet on the subject. Anyone interested will receive a sample from the above firm on application.

Monthly Stock List. The December list of new and second hand engines, boilers, steam appliances and other power equipment, iron and woodworking machinery, has been issued by H. W. Petrie, Toronto. This list covers a wide range and is very complete. It may be had for the asking.

Cooley Engines. A pamphlet given to a type of rotary steam engine being placed on the market by the Cooley General Development Selling Co., Boston, Mass. These run from 1 1-2 horse power, with a weight of four pounds to twenty-nine horse power, weighing 835 pounds; the price ranging from $25 to $250. This is something very much out of the ordinary in the way of a steam engine. 15 pages, 3 1-2 x 6 inches.

Punching Machines. Literature including circulars and pamphlets is being sent out by Edwin B. Stimson & Son, New York, showing the different styles of punches made by them.

Portable Tools. H. B. Underwood & Co., Philadelphia, manufacturers of portable tools for railway repair shops, have issued a well illustrated catalogue dealing with the special tools manufactured by them. These cover a very wide range and are applicable not only to railway repair shops, but other shops as well. They include some very special apparatus of their own design and make, so that anyone having occasion to use tools for repair should send for a copy of this catalogue. 36 pages, 6 x 9 inches.

Gisholt Tools. Two bulletin circulars have been received from the Gisholt Machine Co., Madison, Wis. One of these describes the Gisholt motor driven boring mill of new design. The other takes up their motor-driven lathes, showing how they may be motor equipped. A commendable feature of these bulletins is that they are sent out in the form suitable for binding and thus more easily kept. Size, 8 x 10 inches.

Bulletin of the Imperial Institute. No. 2 of Vol. 3 of the Bulletin of the Imperial Institute, South Kensington, has been received. Besides the Indian and colonial collections, this is devoted to scientific and technical investigations, general notices respecting economic products and their development, notes on recent literature and library, containing in all a large amount of useful information.

Woodworking Machinery. The large catalogue of Jackson, Cochrane & Co., Berlin, Ont., contains complete information regarding their improved and patented woodworking machinery. It covers the entire range of the woodworking field, the illustrations being large, and therefore the details are brought out in a very satisfactory manner. It contains over 100 pages and is printed on heavy coated paper. Size, 9 1-2 x 12 inches.

Economy. An article published by the Murphy Iron Works, Board of Trade building, Toronto, on the economy of cost for power and smoke prevention, giving a great deal of information regarding the conditions in connection with using boilers, and also pointing out how coal may be saved in using the Murphy boiler. Size 6 by 9.

Westinghouse Standard Engine. An art catalogue of 35 pages, describing the standard steam engine built by the Westinghouse Machine Co., East Pittsburg, Pa. The illustrations contained are of a high order, in keeping with the literature usually issued by this company. Illustrations are given of different parts as well as sectional views of the vital features of the engine. Everyone interested in engines should have a copy of this. Size, 6 inches by 9 inches.

Water Lifted by Compressed Air. This catalogue has been received from the Ingersoll Sergeant Drill Co., and besides describing with full complement of illustrations the subject mentioned, it gives a large amount of valuable information regarding the arrangement of wells and piping and the different applications of air compressors. 95 pages, 5 by 9 inches.

Water Softener Plants. A technical and well illustrated description of the water softening and sterilizing apparatus manufactured by the St. Lawrence Water Softener & Sterilizer Co., Limited, London, Eng. Its application to use for town supply and for public and private use is also dealt with. 38 pages, 6 by 9 1-2 inches.

The Smart-Turner Machine Co., of Hamilton, have recently supplied automatic feed pumps and receivers to the Beek Mfg. Co., Penetanguishene; the London Machine Tool Co., London; Wilson Scale Works, Toronto; John Bertram & Sons, Dundas; the Iron Mask Mine, British Columbia; H. K. Wampole Co., Perth.

Practical Questions and Answers

Kinetic Energy.

Ques.—What is the kinetic energy for a rotating body, and how is it computed?

Ans.—The kinetic energy for a body with a motion of translation was discussed in a recent issue of Canadian Machinery, and it was found that choosing suitable units :

$$K.E. = \frac{m\,v^2}{2}, \text{ where}$$

m = mass of the body,

v = velocity.

In a rotating body we have to deal with angular velocity instead of velocity in a straight line, and with the "moment of inertia" instead of with the mass. The formula for the kinetic energy of a rotating body is :

$$K.E. = \frac{I\,\omega^2}{2}$$

where I = moment of inertia of the body,

and ω = angular velocity in radians per sec.

Both of these terms will need some explanation.

First, consider angular velocity. Angular velocity may be measured, and generally is measured, in revolutions per minute, or it may be measured in radians per sec. In one revolution there are 2π radians; that is 360 degrees, a complete rev., is divided into 2π parts, each part being called a radian. Thus, to change a number of revolutions per minute into radians per sec., the number should be multiplied by $\frac{2\pi}{60}$.

To understand the term "moment of inertia," consider a small mass at the end of a string rotating about a centre. The moment of inertia of this body will be its mass multiplied by the square of its distance from the centre of rotation.

Thus the kinetic energy of a small lead ball weighing 0.25 pounds rotating about a centre 2 feet distant at 50 rev. per minute would be :

$$K.E. = \frac{I\,\omega^2}{2} = \frac{0.25 \times 4}{2} \times \left(\frac{50 \times 2\pi}{60}\right)^2$$

foot pounds, = 13.52 foot pounds.

In this example it is simple to find the moment of inertia, but where the mass is in the form of a disk, the centre of the disk being the centre of rotation, or of some modification such as a flywheel, it is more difficult. However formulas have been deduced for the finding of the moment of inertia of different shaped bodies, and these formulas are contained in most mechanical pocket books. For instance, the moment of inertia for a circular disk rotating about its centre is given by the formula :

$$I = \frac{m\,a^2}{2},$$

where m = mass of disk,

and a = radius.

* * *

Boiler Heating Surface.

Ques.—In steam boiler making what is considered as heating surface?

Ans.—The general conception of heating surface among boilermakers at the present time is any surface which is exposed to water on one side, and fire or hot gases on the other side. No discrimination is made between heating surfaces because of the greater effectiveness of one over another, except that in the design of a boiler the tube surface is made not less than a certain percent of the total heating surface, depending upon the style of boiler.

There is considerable difference of opinion as to whether the tubular surface should be reckoned from the inside or outside diameter. Because the outside diameter of tubes are standard it is more or less general practice to reckon the heating surface from the outside diameter because of the greater ease of computation, but since the resistance to the passage of heat from the hot gases to the water is practically all due to the resistance of the metal, it would seem to be more correct to reckon as the heating surface that next the hot gases, i.e., from the inside diameter in fire tube boiler and from outside diameter in water tube boiler.

* * *

Horse-Power for Lathes.

Ques.—Are there any formulas in existence from which the power required to run lathes can be found?

Ans.—There are such formulas made up from tests conducted by different men. However, because of the extreme variance in the make of large lathes, it has been found impossible to deduce a formula which will give at all approximate results for the horse-power. But for the smaller lathes, say under 20-inch swing, there are formulas giving approximate results.

The power required to drive a working lathe depends upon the power required to drive the lathe empty, upon the nature of the material being machined, upon the amount of metal removed in a given time, and upon the shape of the cutting tool.

The following formulas are given by Kent, in his hand-book for finding the horse-power required to drive lathes under 20 inch swing running empty :

(1) Back gears out :

H.P. = 0.095 + 0.0012 N

(2) Back gears in :

H.P. = 0.10 + 0.006 N,

where H.P. = horse power,

and N = revolutions of spindle per minute.

The power required to remove metal can be determined more accurately and without regard to size of lathe. The following formula is given by Dr. Hartig for this :

H.P. = C.W, where

C = constant for different material,

and W = weight in pounds of the chips removed per hour.

In obtaining the constant "C" for the different materials an average value was taken of experiments with various shaped tools. Values of "C" are :

Cast iron — C = 0.030

Wrought iron — C = 0.032

Steel — C = 0.047

The total horse-power required would be the sum of the two.

* * *

Proportions of Keys.

Ques.—Can you supply me with formulas for the dimensions of the different kinds of keys in terms of the diameter of the shaft?

Ans.—The following emperical formulas correspond to general practice :

d = diam. of shaft.

b = breadth of key,

and t = mean thickness.

Sunk keys :

b = 0.21 d + 0.04,

t = 0.12 d + 0.04.

Feather keys :

b = 0.12 d + 0.125,

t = 0.15 d + 0.06.

Keys on flats :

b = 0.25 d,

t = 0.08 d.

The taper of keys varies from 1 in 64 to 1 in 100.

These emperical formulas assume that the total amount of power carried by the shaft is transmitted through the one key; and thus, if power is taken off at various points along the shaft, the dimensions for the keys for the pulleys taking off this power at the several points would be unnecessarily large. The exact dimensions necessary for the keys in the different cases can only be determined by computation from the horse-power taken off at the various points.

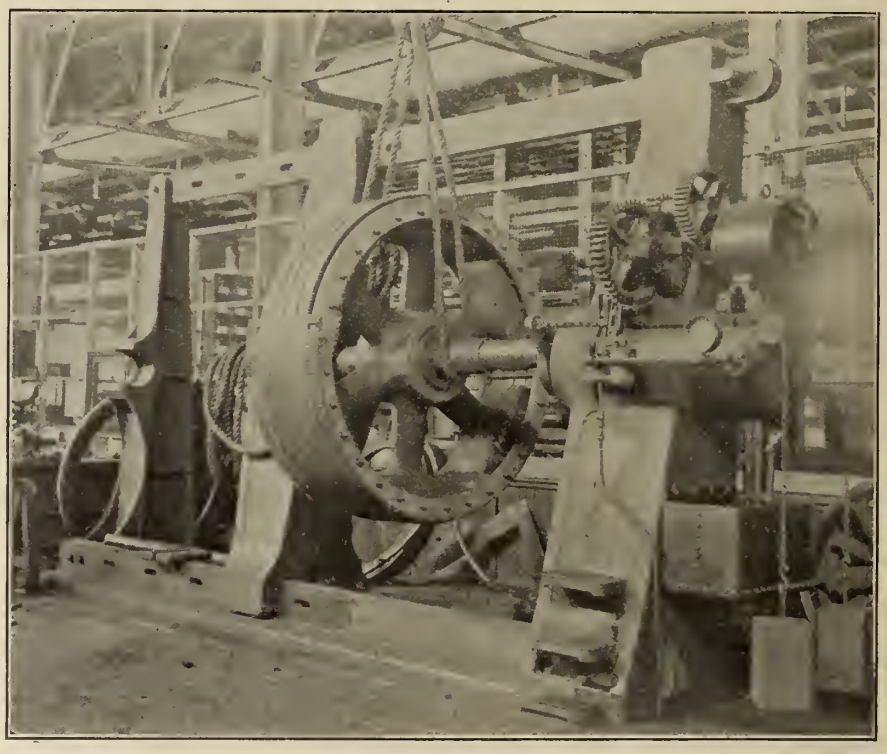
Machinery Development

Metal Working **Special Apparatus** **Wood Working**

200 TON HYDRAULIC PRESS

THE machine here described and illustrated, has been recently installed at the works of the Allis-Chalmers-Bullock, Limited, Rockfield, Que., by the John McDougall Caledonian Iron Works, Montreal.

Prominent in the design is the space of the longitudinal tension bars, the inclination, 30 degrees, of the whole upper structure, the massive proportions of the strain bearing units, the compactness of management and the ease of manipulation. The outfit is primarily intended for pressing rotor and armature spiders on to the shafts of the larger electrical machinery and the determination of the space, 10 feet, between tension bars, was arrived at by providing for the handling of a revolving element belonging to the largest machine that the present equipment of the Rockfield works can otherwise just at present undertake. Since the installation of the press, its full capacity between the tension bars has been taxed and the highest satisfaction is being had under all conditions of operation and varieties of work. The idea of inclining the upper structure is to permit of the crane hook and sling passing clear of the upper tension bar, thereby enabling the pieces for pressing to be lowered perpendicularly into place without recourse to side or cross pulling and its atendant disadvantages and risks. The machine is entirely self-contained, being mounted on a substantial cast iron base, with provision for permanent molting to a concrete foundation if so desired. The maximum space between ram and resistance head is 20 feet, the overall length, 23 feet 3 inches, the extreme width, 5 feet 6 inches, and the extreme height 13 feet 3 inches. The tension bars are of cast steel, the ram, ram head, resistance and carrier heads being of high tensile strength, cast iron. The ram is 14 inches diameter by 36 inch stroke, operated by a motor driven duplex pump, with all-brass case and plungers, brass valves on steel seats, designed for a working pressure of 2,600 lbs. per square inch. The city water main connects direct to the pump suction, thereby allowing the ram to be run up to its work while the pump and motor are being started. The motor, an A-C-B, 5 H.P., 240 volts, 1,050 1.p.m. transmits its power to the pump driving shaft by double reduction machine cut gears, reducing the speed at the pump to about 100 strokes per minute. The ram is fitted with one ordinary cup leather ring and is arranged to return automatically by means of counter balance weights when the release valve is opened. A pin safety valve with lever and weight, a pressure gauge registering tons load and pounds per square inch on sectional area of ram, give a necessary finish to the hydraulic equipment. The resistance head has a carriage attachment at its lower end, having wheel rollers with large bearing surfaces, which together with the rollers on the upper tension bar, make this unit easy of movement in either direction by hand power alone. The complete machine weighs 52,000 lbs. and although of extreme dimensions, is arranged for easy access to and manipulation of all parts with a minimum of labor. It is therefore suitable for work of a varied nature and is a valuable addition to the plant of any up-to-date engineering or electrical establishment. It occupies a small floor space and being self-contained can be set in a corner. The material is all special of its kind, tested for strength, and the workmanship such as to reflect the greatest credit on the builders. The successful issue of the work, which marks a new departure for the John McDougall Co., is but one more instance of the hidden resources of the engineering profession in this Dominion and of the growing desire to unearth these resources, so as to be able to take up competition with the older established concerns, of other countries, and why not?



200-Ton Hydraulic Press.

TAYLOR-McKENZIE PUNCH.

In a reference to this punch in last issue the paragraph referring to the capacity of the machine read "capable of taking bent iron" instead of "capable of taking hand iron." This firm make wood lathes amongst other wood-working machinery instead of wide lathes as printed before.

AN INTERESTING STORY.

IN connection with the machine illustrated herewith, there is an interesting story attached. The device shown is an installation in the work of the Niles Tool Co., of Hamilton, Ohio, made by the Pilling Air Engine Co., Detroit, Mich., and is told in the words of Mr. J. L. Pilling, as follows:

"You know the Niles Tool Co. build some very large planers and lathes, and the 'V'-shaped groove upon which the planer and the head of the lathe travel have to be emeried down, for which purpose they have a saddle which weighs according to the size of the lathe. But one time while I was in Hamilton, they had a two-ton saddle and four men at each side, pulling back and forth the saddle to smooth down the groove of the planer. I went home, designed the machine of which you have a half-tone, and sent it down to them, not saying a word. In about two months I went down there and told them that a clerk had shipped a machine by mistake and that I had come after it. They asked me to describe it. I told them what it was, and they said if I undertook to take that machine out of there I would get shot. That braced me up in such a manner that I asked and received a third more for the machine than I intended to charge upon my entrance into their shop. They use that device for various purposes. They haul it around the shop and use it for hoisting, and moving cars (which run right through the shop), and it has proved to be a valuable investment to them."

RETURNED JAN 15 1906

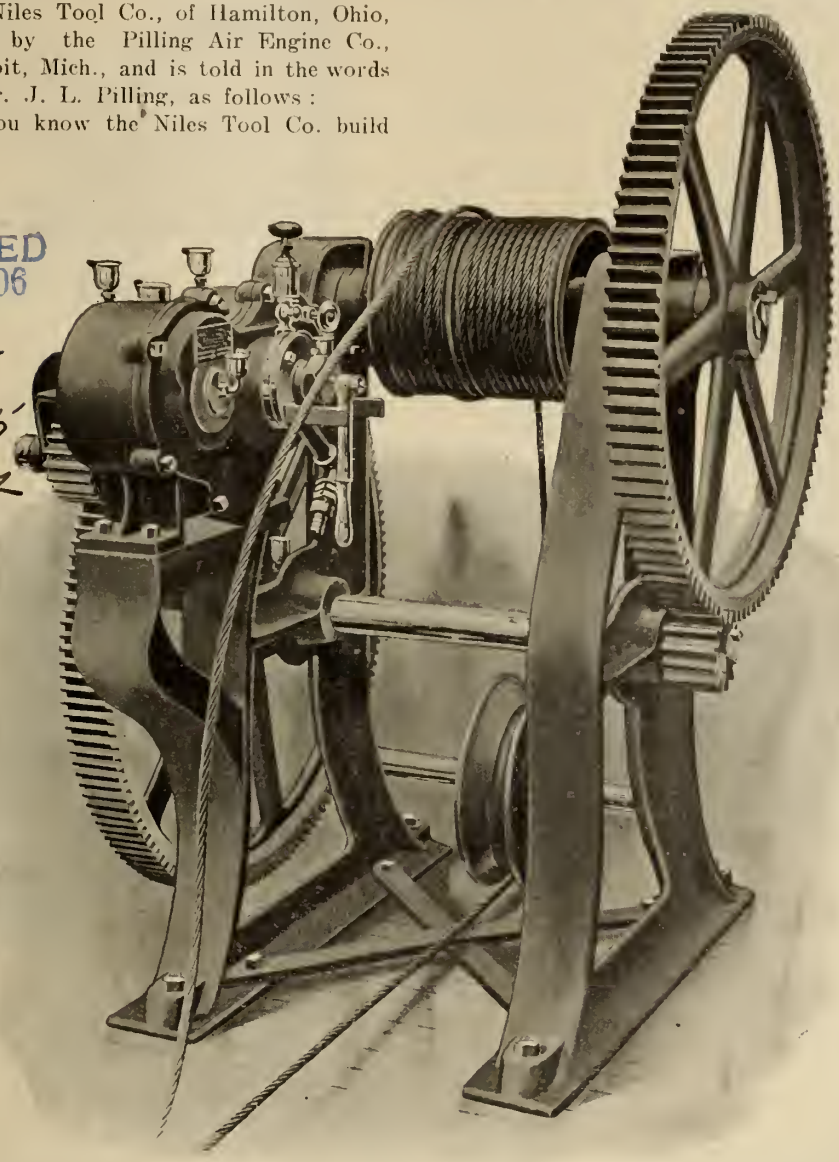


Fig. 3.—An Equipment for Traversing Heavy Parts of Machine Tools.

CINCINNATI SHAPER PARTS.

RECENTLY the Cincinnati Shaper Co., of Cincinnati, became established in their new shop, situated on a 3½ acre tract of ground in the heart of the machine tool industry, giving them better facilities than ever for turning out a high-grade product. They have devoted particular attention to the manufacture of shapers of the pillar or column and traverse head types, their attachments, etc., and to a new line of traverse grinders, in connection with which they have gone liberally into jigs and special appliances to secure a high standard of accuracy.

RETURNED JAN 15 1906

Fig. 1.

Some of the parts as illustrated herewith will give readers a better idea of the details and extra attachments provided for these shapers. In Fig. 1 is illustrated the variable automatic power down feed, which is furnished with the traverse shaper, being adjustable for position of slope and being independent of spring is positive in action. A blank boss is left on the rams of all pillar shapers, so that this attachment may be supplied subsequently. Fig. 2 shows the concave attachment which can be operated in any position of the ram, namely, close to or away from the column. It is positive in its action, and by varying the position of the down slide will work concave surfaces of different radii. The revolving table is shown in Fig. 3, which is particularly useful in die work of a complicated nature. It permits, with a swivel base, vise holding a piece of work at any compound angle. It is revolved on a trunnion by means of a pinion and gear, and has a motion of

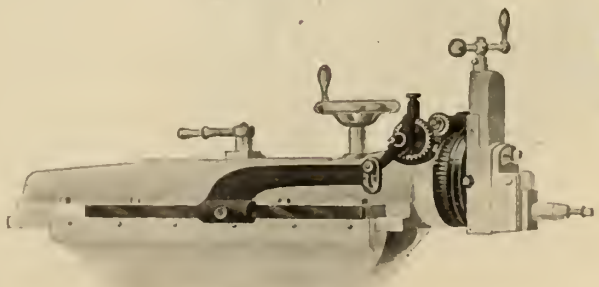

Fig. 2

90 degrees in either direction. In Fig. 4 the tilting table is shown. It is firmly hinged at the top of the apron and is held in an angular position by means of links, shown, and compression screws

Fig. 3.

through the table from impinging against the apron. In Fig. 5 the tilting top for tables is shown hinged to

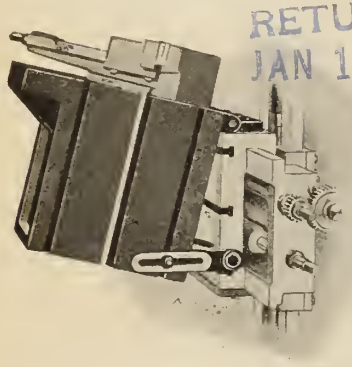

Fig. 4.

the apron. It may be angled and firmly bolted as shown in the illustration. It has independent sides to allow for operating the vise stud nut beneath when in a horizontal position. This attachment is readily removable for restoring the machine to the original form of table. The 10-inch swing cone arbor for attaching to the table, designed for either hand or power feed, is shown with power feed, and in Fig. 7 the 16-inch swing cone arbor for attaching to the apron is illustrated. It is likewise made for hand and power feed and, like the other, is shown with power feed. In Fig. 8 may be seen the full swing cone arbor for attaching to the apron, and which affords unusual range for work of large diameter. For heavy work the arbor may be supported at the outer end. When made for hand power only the power feed parts are omitted and the shaft is turned by means of a crank.

LATEST RADIAL DRILL.

IN this machine is represented the latest product of the Bickford Drill & Tool Co., of Cincinnati, Ohio. Its capacity for drilling from the solid is rated at 2 inches for steel and 2½ inches for cast iron. Of new design throughout, the tool contains many improvements over its predecessors, but its chief characteristic lies in the speed box which, without the back gears or a clutch of any kind, gives instantly, with a single lever, six changes of speed.

Referring to the diagram, it will be seen that the speeds are obtained by means of a primary shaft (c) which turns fixed gear (d) and sliding gear (b), a tumbler plate (a) which fulcrums on shaft (c) and carries an intermediate gear (e) for transmitting power to any one of the fixed gears (g), (h), (i), (j), or (k), an intermediate gear (f) for transmitting continuous motion from fixed gear (d) to loose gear (l), which carries a pawl and runs on the hub of a ratchet keyed to secondary shaft (m), and a device for automatically engag-

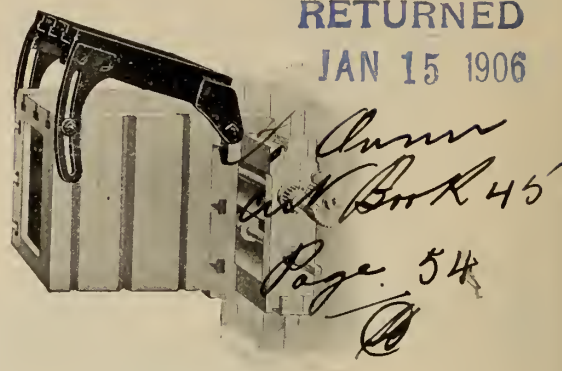

Fig. 5.

ing the pawl or keeping it away from the ratchet.

The slowest speed is obtained by sliding the tumbler plate (a) to the last notch on the right, when the intermedi-

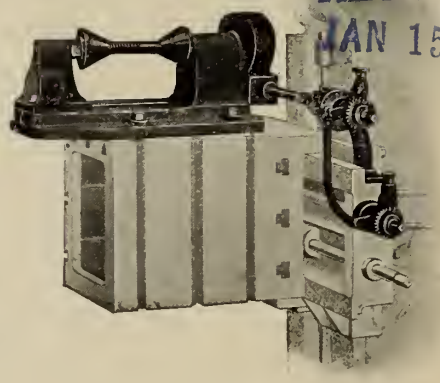

Fig. 6.

ate gear (e) occupies the space between gears (k) and (l), and the power is transmitted to shaft (m) through gears (b) and (l). Moving the tumbler plate to the next notch brings intermediate

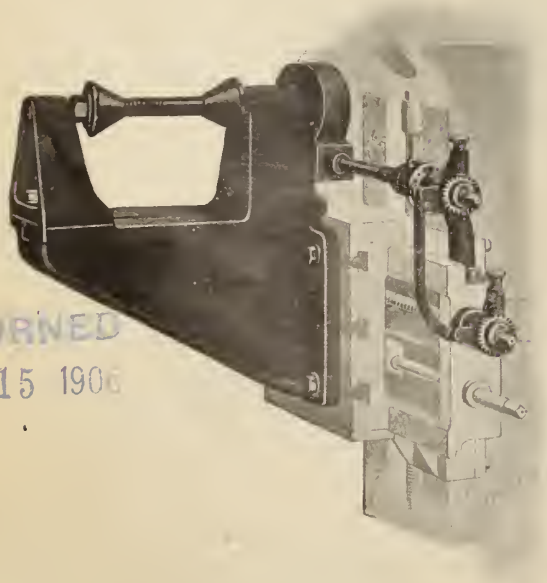

Fig. 7.

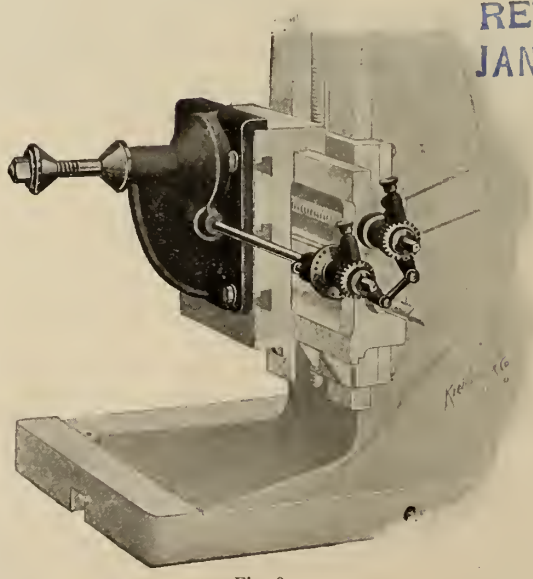

Fig. 8.

gear (e) into engagement with gear (k), which makes gear (b) the driver and causes the ratchet on shaft (m) to run away from the pawl in gear (l). Shaft (m) is, therefore, always running, for the moment its speed drops below that of gear (l), the pawl in gear (l) acts automatically and keeps it turning at its minimum speed until gear (b) is again made the driver.

As the minimum periphery speed of the smallest driven gear (g) is but 182 feet less than the periphery speed of driving gear (b), the shock which usually accompanies engaging gears broadside is reduced to a minimum, such shock as there is being absorbed by the belt. Another good feature of this drive is the high belt speed attainable at low gear speeds. Shaft (e) runs at 350 revs. per min., while the perpiphery speed of no gear in the box exceeds 301 feet per min.

This speed-box, augmented by the back gears on the head, gives the machine twelve changes of speed, the range and gradations of which are shown in the following table :

No. of revs. per min. made by spindle.	Diam. of drills for which speed is suitable.	No. of feet per min. at which drilling is done.	No. of feet per min. at which drilling should be done.
265.09	$\frac{1}{2}$	34.60	35.0
209.86	$\frac{5}{8}$	34.34	34.3
173.68	$\frac{3}{4}$	34.10	33.6
143.91	$\frac{7}{8}$	33.07	32.9
122.84	1	32.16	32.2
104.29	$1\frac{1}{8}$	30.72	31.5
95.41	$1\frac{1}{4}$	31.22	30.8
75.53	$1\frac{1}{2}$	29.66	29.4
62.51	$1\frac{3}{4}$	28.74	28
51.79	2	27.12	26.6
44.21	$2\frac{1}{4}$	26.04	25.2
37.56	$2\frac{1}{2}$	22.56	23.8

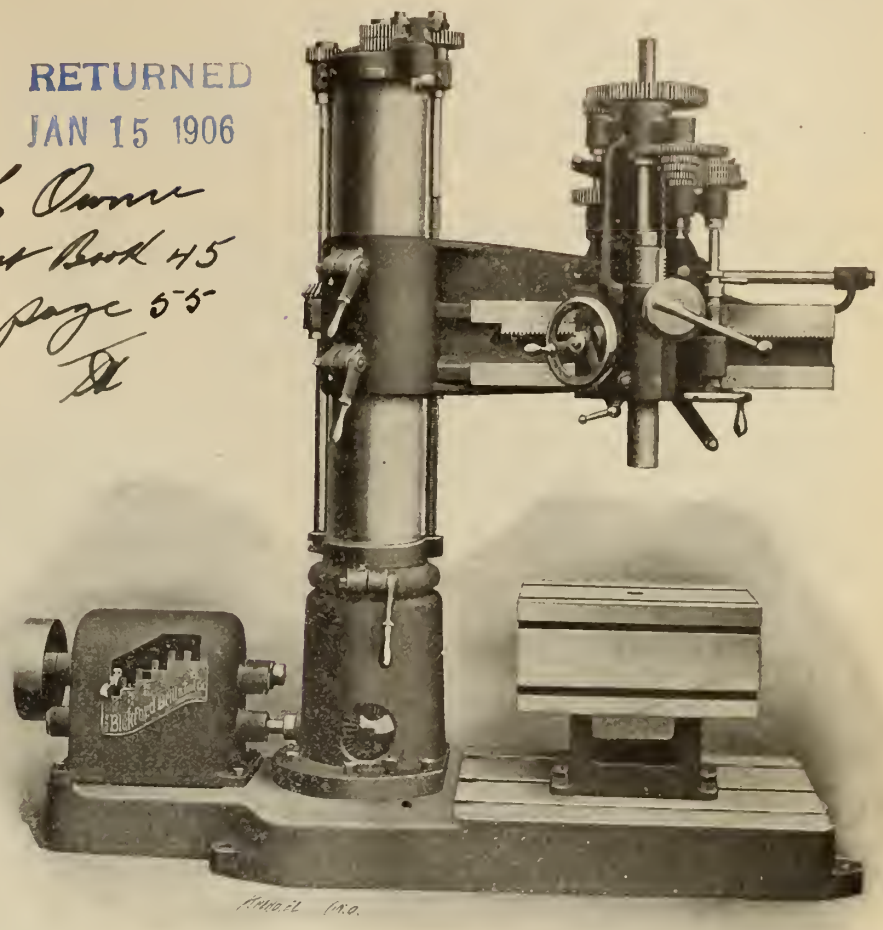
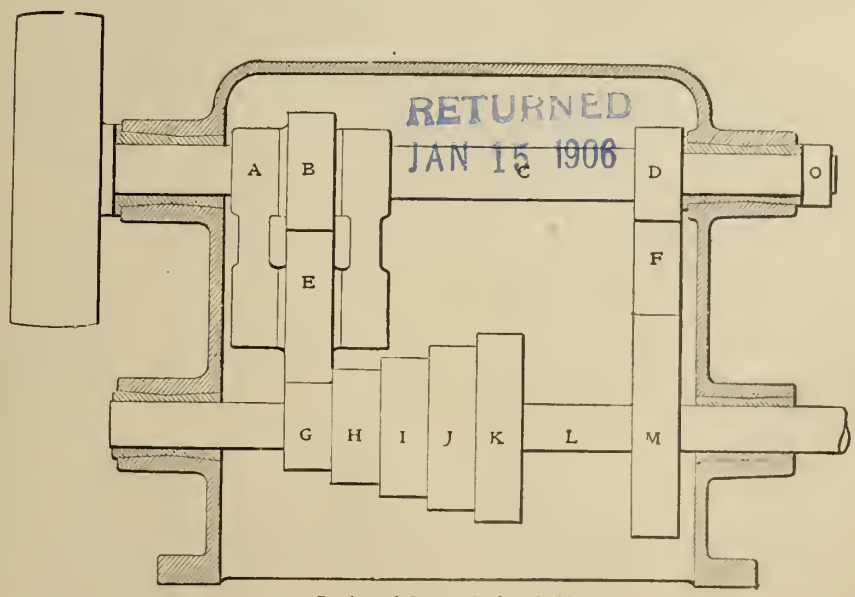
Out Book 45
page 5-5-



3-ft. Bickford Radial Drill.



Section of Gear, Bickford Drill.

A comparison of the figures in the third and fourth columns indicates that the manufacturers have exercised their customary care of the selection of gears, as in no instance do the cutting speeds vary from the theoretically correct by more than .84 of a foot per minute. Another point to which our attention has been called is the irregular gradation of the speeds. The stock expression that "the speeds are in true geometrical progression" has become so common of late that many tool builders appear to think that no series other than a geometrical series is correct. That this is an erroneous belief is well exemplified in the example before us.

For the speeds to be in geometrical progression they would have to coincide with the following series of numbers :

Geometrical Series.	Diameter of Drills.	Periphery Speeds.
265.09	$\frac{1}{2}$	34.60
221.90	$\frac{5}{8}$	36.31
185.81	$\frac{3}{4}$	36.48
155.54	$\frac{7}{8}$	35.63
130.26	1	34.10
109.04	$1\frac{1}{8}$	32.12
91.31	$1\frac{1}{4}$	29.88
76.13	$1\frac{1}{2}$	30.01
64.00	$1\frac{3}{4}$	29.32
53.60	2	28.06
44.85	$2\frac{1}{4}$	26.41
37.56	$2\frac{1}{2}$	24.56

An inspection of the table will show that instead of giving a series of cutting speeds in which no speed is more than .84 of a foot too high, nor .87 of a foot too low, the cutting speeds in the geometrical series come "any-old way" from 2.88 feet too high to .92 of a foot too low. In the one case the maximum error is but 2.47 per cent., and the average error but .831 per

cent.; while in the other the maximum error is 8.57 per cent., and the average error 3.903 per cent., or more than four and one-half times greater.

The machine is also furnished with a five-step cone drive, a constant or variable speed motor drive, a swinging or swiveling table, and a round or double-end base.

A WONDERFUL DIGGER.

The country west of Montreal is being rapidly prepared for suburban residences, and roads are being opened up through many orchards and fields by a real estate company, which is exploiting this district. One of the most important factors in this process is a machine owned by the J. W. Harris Co., Limited, of Montreal, which is at present operating on the Upper Lachine road, just above the new G.T.R. roundhouse at Turcot.

This machine, which cuts a trench three feet wide and eight to thirteen feet deep, for water mains, carries the earth and stones back sixty feet, and refills the trench as quickly as men can lay the pipes. It has a long arm with a number of buckets or scoops revolving inward, which scoop up the earth, carry it up, and dump it on a moving table, which carries it back sixty feet and refills the drain. Or, if so desired, it can be adjusted to carry the earth to one side.

This machine is operated by a powerful sixty h.p. engine, is self-propelled, and can be moved from one place to another under its own steam, at the rate of three miles an hour. It can do the work of two hundred men, and experts who have seen the machine working pronounce it the greatest machine they ever witnessed.

UNIVERSAL MILLING MACHINES.

THIS machine, manufactured by the Becker-Brainard Milling Machine Co., embodies a number of new and important improvements which will be much appreciated by users of Universal milling machines. Special attention is called to the positive gear feed drive and the change feed mechanism, by which twenty changes of feed can be made without stopping the machine, the new clutch mechanism in connection with the hand wheels, also the box type of knee and telescopic elevating screw.

The spindle has a No. 10 B. & S. taper hole in front end, is made of hammered crucible steel, has a ¾ inch hole through its entire length and runs in self-centering bronze boxes arranged to compensate for wear. It has slot across end to engage clutch collar for arbor, is threaded to take a chuck, and a threaded collar covers the screw when not in use. It is connected with the change feed mechanism by three spur gears, making a positive drive. The spindle is fully back-geared, and gears are protected by guards. The arm is made of steel, is designed for horizontal adjustment and has an arbor support which may be removed, so that any of the attachments can be placed in position without the necessity of removing the arm. The table has an automatic longitudinal and cross feed in either direction and being centrally driven, feeds freely at any angle to 45 degrees right or left hand. It is provided with 3-5-8 inch T slots and with oil pans at each end. Feed is reversed in front of machine. The knee is of the box type and is supported by a telescopic elevating screw, so that no holes are necessary in the floor. Hand wheels are provided with clutch arrangement enclosed in hub which operate the vertical movement of the knee and cross movements of the carriage. When either the knee or carriage have been set to the required position, the clutch may be instantly disengaged by pressing in the knob on the front of the hand wheel, thereby preventing any accidental change from their fixed position and also preventing them from revolving when the automatic feeds are thrown in. Dials are adjustable and graduated to read to thousandths of an inch., to indicate the vertical, transverse and longitudinal movements of platen, and are set at any position with set screw. The patented change feed mechanism is conveniently arranged on the back of column and is capable of obtaining instantly, twenty changes of feed, slow or fast, by a simple movement of the lever, without stopping the machine.

Becker-Brainard Milling Machine.

ONE'S POSSIBILITIES.

Insist on yourself; never imitate. There is at this moment for you an utterance brave and grand as that of the colossal chisel of Phidias, or the pen of Moses or Dante, but different from these. If you can hear what these patriarchs say, surely you can reply to them in the same pitch of voice.—Emerson.

WATER POWER OF THE OTTAWA.

On the Ottawa River there is at present available an enormous water power of which, generally speaking, little is known beyond the Chaudiere.

The Chaudiere is but one of the water powers of the Ottawa and but few realize the enormons extent of the power in water falls and rapids as the river approaches its source. At the Chaudiere there is a drop of 33 feet. Five miles above this is the Duchesne Falls with a drop of 12 to 14 feet, all the water of the Ottawa passing over it. At a distance of about 28 miles farther up, or 33 miles from Ottawa, is the Chats Falls, where there is a drop of at least twice that of the Chaudiere. Between Chats Falls and Mattawa there are half a dozen rapids. Other rapids above Mattawa are Le Cave with a drop of about 10 feet, then Les Arables 6 miles farther which have a drop of about 11 feet in half a mile. At Mountain Rapids 4 miles above Les Arables the river becomes very narrow and a drop of 12 feet takes place in such a short distance as to make it practically a fall. The last pitch in the Long Sault Rapid occurs 21 miles above Mountain Rapids, where there is a drop of 12 feet, the 5 miles above this being an almost continued succession of rapids. At the first pitch of the Long Sault there is 8 feet of a drop. At this point Lake Temiskaming starts and here Gordon Creek tumbles into the Ottawa at the first pitch of the Sault Rapids. Near by Temiskaming station is located. Gordon Creek runs from Lake Kippewa and in 9 miles drops 300 feet; in the first mile and a quarter there is 250 feet of a drop and although it is called Gordon Creek it is really a river of considerable volume. The next river emptying into Lake Temiskaming is Opimicon Creek, which though not large in volume drains numerous lakes, amongst which is Emerald over 3 miles long by half a mile wide. It has two falls close together which would total 100 feet. The mouth of the Opimicon Creek is 12 miles from Temiskaming station, 29 miles from which the Kippewa River enters the lake. Like Gordon Creek it also drains Lake Kippewa and has a fall of about 350 feet in rapids. On the west side of the lake, 38 miles from Temiskaming, the Montreal River enters through a narrow gorge, 13 to 16 feet in width. All that would be necessary to develop the water power here would be to cut a niche in the rock and put in stop logs. A head of 75 feet could easily be used, while at the same time there is a large volume of water available. Farther up is La Vallee Creek where one of its water powers is already developed, a saw mill being situated thereon. This is 43 miles from Temiskaming. Twenty-seven miles further up a small river, the Otter, runs into the lake near its head. On this there is a small water power developed. Coming to the headwaters of Lake Temiskaming we have the Quinze River (river of fifteen rapids). It flows from Lac des Quinze, a distance of 28 miles, during which there are 15 rapids. The first rapids drops 18 feet, almost a fall. There is a very large volume of water here, but the lease has already been given for this water power for pulp mills.

These constitute the falls of the Ottawa above the city itself, while immediately below is the Rideau, where the Rideau River drops 65 feet into the Ottawa. Then there is the Gatineau River whose headwaters are the same as those of the Ottawa, consequently the drop of the Gatineau must be the same, and therefore the water power will be in an equal ratio to their volumes. This gives the reader some idea of the possibilities for water power development in the vicinity of the Ottawa and there is no doubt that a few years will see industries in large numbers grouped about these centres of economical power.

The Metabechouan Falls, Quebec.

Companies Incorporated

The surrender of the charter of the W. G. Nott Bicycle Co., of Brantford, has been accepted.

Manitoba Peat Co., of Winnipeg, has been authorized to manufacture, sell and deal in peat and all kinds of fuel.

The Borland Carriage Co. have been granted the privilege of increasing their capital from $25,000 to $250,000.

Rhodes Metallic Packing Co., Toronto, share capital $40,000, purpose to deal in engineers' supplies. The directors are: J. M. Rhodes, J. S. Dawson and R. L. McAfee, all of Toronto.

Western Machine Co., Toronto, share capital $40,000, purpose to deal in all kinds of machinery. The directors to be: G. McLachlan, B. Thompson and W. T. Folliott, all of Toronto.

St. Mary's Hardware, St. Mary's, share capital $40,000, purpose to carry on a wholesale and retail hardware business. Directors: J. W. Peart, W. H. Bartlett and N. Mulloy, all of St. Mary's.

The Stephenson Belting Co., Toronto, share capital $40,000, purpose to deal in machinery, etc. The directors are: J. E. Stephenson, W. Stephenson, B. G. Stephenson, W. Gillespie and Mary Stephenson, all of Toronto.

Majestic Polishes, Toronto, share capital $40,000, purpose to manufacture, buy and sell oils, varnishes, paints, etc. The directors are: C. G. Armstrong, J. Hawken, D. R. Roy, T. H. Wilson and G. R. Brady, all of Toronto.

Toronto-Cobalt Mining, Toronto, share capital $300,000. purpose to carry on the operations of a mining, milling and development company. The directors are: H. B. Wills, W. Vandusen and J. S. Humberstone, all of Toronto.

The Eastern Coal Co. have been further incorporated to carry out and transact all matters and things comprised within the powers of the company. A. Alfred Laurie, Toronto, has been appointed attorney for the company.

Sovereign Cobalt Mining Co., Toronto. share capital $200,000, purpose to carry on the operations of a mining, milling and development company. The directors are: P. M. Horrocks, W. A. Smiley and F. J. Stanley, all of Toronto.

Petrolia Gas Co., Petrolia, share capital $40,000, purpose to manufacture and sell artificial and natural gas for all purposes. Directors: W. C. Noxon, E. Noxon and C. Swabey, of Toronto, and J. W. McCutcheon and B. McCutcheon, of Petrolia.

Schaake Machine Works, New Westminster, B.C., share capital $1,000,000, purpose to do general machine construction work. The directors are: Alex. Ewan, Henry Schaake, Dr. A. J. Holmes, Nels Nelson, and E. J. Fader, of New Westminster.

The Canadian De-Tinning & Chemical Co., Montreal, share capital $100,000, purpose to manufacture and deal in all kinds of chemicals and chemical products. The incorporators are H. H. Wolff, J. Wolff, A. Pollack, A. Bover, and H. J. Hague, all of Montreal.

The George Tucker Co., of Canada, Montreal, share capital $40,000, purpose to manufacture and deal in all kinds of stationery supplies and hardware sundries. The incorporators are J. H. Hough, W. H. Butters, F. R. Lanigan and H. Pillow, all of Montreal.

Economical Mfg. & Supply Co., Toronto; share capital $40,000; purpose, to manufacture and deal in engineers' and steam users' supplies. The directors are H. L. Brown, W. J. Boland, Samuel Behan and T. J. Walsh, all of Toronto, and W. H. Crow, of Welland.

Canadian Forty-Mile Dredging Co., Toronto, share capital $600,000, purpose to build, acquire, own, charter, navigate and use steam and other vessels. The incorporators are: J. S. Lowell, W. Bain, R. Gowans, E. W. McNeil, S. G. Crowell, W. F. Ralph, all of Toronto.

The Perry Lubricator & Machine Co., Ottawa, share capital $250,000, purpose to manufacture, buy, sell or deal in machinery or mechanical devices. The incorporators are J. Walker, A. Wilson and A. Berry of Montreal, and E. A. Bleakney, W. Gamble and F. A. Heney, of Ottawa.

The Twin City Brick & Supply Co., Port Arthur, share capital $40,000, purpose to manufacture, sell and dispose of cement and all kinds of bricks and building material. The directors are to be J. A. Stewart, H. Finger, E. McEwen, T. H. McCauley and J. McCutcheon, all of Port Arthur.

Imperial Electric Motor Co., Toronto, share capital $200,000, purpose to manufacture, sell, lease and dispose of power machinery and automobiles, etc. The directors are: A. Dods, R. McKay, G. Grant, Winnifred F. McIntosh, Agnes Elliott, A. E. Lyon and A. L. Bitzer, all of Toronto.

Stinson-Reeb Builders' Supply Co., Montreal, share capital $20,000, purpose to manufacture and deal in cement, lime, brick, stone, etc. The incorporators are: J. K. Stinson, F. J. Curran, and E. H. Stinson, of Montreal, J. A. Reeb, Port Colborne, and H. W. Macoomb. of Welland.

The Ontario Car Ferry Co., Montreal, share capital $500,000, purpose to carry on a general business in steamships, tugs, barges, ferry boats, etc. The incorporators are C. M. Hayes, F. H. Fitzhugh and J. W. Loud, of Montreal, and A. G. Yates, W. T. Nooman and R. W. Davis, of Rochester, N.Y.

Parker Foundry Co., Montreal, share capital $25,000, purpose to carry on the business of founders and manufacturers of castings, plumbers' supplies, machinery, etc. The incorporators are J. Ballantyne, H. W. Glassford, of Montreal, and M. C. Rosenfield, Cleveland, Ohio, W. J. White and A. W. P. Buchanan, of Montreal.

The Maritime Gasoline Engine & Supply Co. has been organized at Halifax, with a capital of $50,000, to deal in gasoline engines and power machinery. Agencies will be established in Newfoundland and the West Indies, as well as various places in the Maritime Provinces. Chas. Darlington, Halifax, is to be manager.

The Northumberland-Durham Power Co., Cobourg, share capital $250,000, purpose to construct, maintain, complete and operate works for the production of electricity for the purpose of light, heat and power. The directors are W. J. Crossen, W. J. Maher, F. M. Field, D. Ewing, T. C. Lapp, J. Henderson, A. R. Dundas, and E. C. S. Huycke, all of Cobourg, J. A. Culverwell, W. McLean, R. A. Mulholland, J. F. Clark and F. W. Galbraith, all of Port Hope, Charles Donnelly of Pittsburg, Pa., S. Nesbitt of Brighton, E. T. Adams, of Toronto, and R. A. Elliot, of Roseneath.

Millionaire Schwab's Views.

"In the next ten years," said Charles M. Schwab recently to a Manhattan professional man whom he was anxious to serve in return for invaluable assistance, "the new big fortunes will be made in mines. My advice to you is to watch out carefully and to get aboard at the earliest possible moment. To-day you can buy for $1 what will cost $5 in two years. I admit all you say of the outlook for railroads; but you must bear in mind that the roads get their money by carrying the industrial output. The two are inseparable. If one is to prosper it is because the other does."

Thus said the first president of the United States Steel Corporation, as he sat in his private car and ejected financial philosophy between the whiffs from an expensive cigar. The present gigantic operations by the "Pittsburg interests" in Nevada gold lands reflect his carefully considered policy; and it is not an accurate description of his mental state to call it a recent change of view brought about by men like John McKane, who is a Canadian, Donald Gillies, Albert S. Watson, Uri Curtis, Chris Zabriskie and George S. Nixon—the picturesque pioneers of the Tonopah region.

Machine Tools Wanted.

For the equipment of their new factory within the next few months the Massey-Harris Co., Limited, Toronto, will be in the market for a large number of machine tools and accessories. These will include not only regular machine tools, but many of special make. The superintendent of the works, Mr. Verity, is about to take a trip where he may see some of these special machines in operation. It is intended to install the best machinery obtainable. Operations formerly carried on by them in Stratford will be carried on in future in Toronto.

Stratford ratepayers will vote on a by-law on January 1st to grant certain inducements to a company to be organized by David Gilchrist of Toronto. The company propose to manufacture wooden boxes, and will invest $40,000 in building and machinery.

INDUSTRIAL PROGRESS

MACHINERY AND MANUFACTURING NEWS would be pleased to receive from any authoritative source industrial news of any sort, the formation or incorporation of companies, establishment or enlargement of mills, factories or foundries, railway or mining news, etc. All such correspondence will be treated as confidential when desired.

A FREIGHT special of 28 cars took the machinery and stock of the Henry K. Wampole Co., manufacturing chemists, from Toronto to Perth last Friday. Nearly 200 men will be employed in the new works at Perth.

A new stave mill has been established at Brigden, Ont.

A soap factory is likely to be established at Berlin.

An extension is to be built to James Bros' foundry at Perth.

The Brantford Malleable Iron Works are to enlarge their works.

Calgary, Alta., has opened its new municipal electric light plant.

The Sommerville Paper Box Factory at Stratford is to be enlarged.

W. S. Dwinnell, Minneapolis, is to establish a saw mill at Strathcona, Alta.

J. K. Fleming, Hartland, N.B., is fitting up a lathe manufacturing plant.

A rich find of gold is reported from the Laurentian mine, near Wabigoon, Ont.

The Canada Glue Co. has changed its headquarters from Toronto to Brantford.

The White Bear Mine at Rossland is installing 400 horse-power electrical motor.

A nugget weighing 250 pounds of almost pure silver has been found at Cobalt.

The British North American Peat Fuel Company is to establish a factory at Winnipeg.

Work on the new Michigan Central Railway tunnel at Windsor has been commenced.

The town of Bracebridge has passed a by-law to spend $14,000 in extending its power plant.

Machine works are to be established at Dauphin, Man., by a company capitalized at $25,000.

A winding-up order has been made regarding the Carleton Foundry Co., of New Brunswick.

The Nipissing Foundry Co., of North Bay, have installed a dynamo to light their own plant.

The Morris Implement Co., Winnipeg, are to establish a branch and build a warehouse at Regina.

The Newville Lumber Co. are rebuilding near Parrsboro, N.S., which was recently destroyed by fire.

Machinery worth $15,000 is being installed at the Mackenzie & Mann iron mines at Atikokan.

Stonehouse & Schuman have began the manufacture of broom handles at Collingwood Corners, N.S.

The Maple Leaf Milling Co. contemplate building a mill between Keewatin and Kenora next Summer.

The Stark Electric Co. are endeavoring to purchase the electric light plant owned by the town of Paris.

In addition to a new depot at London the Grand Trunk are intending to build new freight sheds next Summer.

A new machine shop and other buildings are to be erected by the Dominion Coal Co. at Reserve Junction, C.B.

Moose Jaw's new waterworks system was opened a week ago. The town celebrated the event by a large banquet.

A. C. Thompson's iron foundry at Bridgewater, N.S., suffered damage by fire last week estimated at $23,000.

McGregor, Gourlay & Co., Galt, are advertising their factory building for sale, and may locate in another city.

The Galt Wagon Works Co. are to enlarge their plant. A site has been secured and new buildings are being planned.

The Goodison Threshing Machine Works at Sarnia were damaged to the extent of $10,000 by fire a few days ago.

Owing to a large increase in business the Canadian General Electric Co. are to erect a large warehouse at Montreal.

The town of Saskatoon is likely to be incorporated as a city and to install waterworks and electric lighting systems.

The Patent Roofing Company is being organized at Brantford, to establish a factory to manufacture roofing materials.

Mr. Hannah, a farmer at Griswold, Man., has purchased a site at Brandon and will erect a large hotel there next Summer.

Montreal coal dealers have announced that they will not raise their price above that now current in spite of advances in New York.

American capitalists have been looking for a manufacturing site for an iron industry, which may be established at Cobourg.

Victoria, B.C., is procuring estimates regarding the cost of a power house and machinery capable of generating 1,000 horse power.

Two large turbines are the result of this year's experiment by the Allan line. The plans for these new vessels are now being prepared.

The Amherst Foundry Co. have ordered from the Smart-Turner Machine Co., Limited, Hamilton, a single beam traveling crane.

Cambrian Mineral Co. is being organized for the purpose of erecting a smelter at Sudbury. The capital stock will be $100,000.

The Prepayment Meter Company, Peterboro, are to place orders immediately for machinery to manufacture their patented meters.

The Dominion Iron & Steel Co. has set in motion a new 850 horse power unit, which is the largest of its type in the Maritime Provinces.

The Massey-Harris Co. have closed their branch at Stratford, and will remove the plant to Toronto, in order to centralize their business.

The J. D. Duncan Milk Co. has purchased a site in Montreal, and will erect a three-storey brick and stone building, to cost $50,000.

The Government Diamond Drill now working at Cobalt has reached a depth of 340 feet and it is found that the rock is still rich in native ore.

A wireless telegraph station is being erected at Toronto Junction by the De Forest Co., and it is expected to be in working order early next year.

The B. C. Bedding and Upholstery Company, Vancouver, is to spend $50,000 on machinery and plant for the manufacture of iron and brass beds.

The B. C. Electric Railway Co. are to spend $36,000 for new rolling stock. All of the cars are being made at the company's shops at Vancouver.

The new Banwell-Hoxie Wire Fence Co. have installed their plant on Princess street, Hamilton. The new company is capitalized at $100,000.

Fire did considerable damage to the Granby Mining Company's crusher building at Phoenix, B.C., last Friday night. Arrangements have been made to ship from the old bins at Ironside until the crusher plant and buildings are reconstructed.

The Coal Creek coal mines, below Dawson City, will produce 4,000 tons of coal this Winter. The output will be hauled by the trains from the interior to the river and placed in the bunkers ready for shipment to Dawson early in the Spring.

A company to be capitalized at $4,500,000 is to be organized with headquarters at Dawson City, to install a gigantic hydraulic system for operating on the creeks tributary to Dawson. This is the largest mining proposition yet in the Klondike.

The Delaware & Hudson Railway Co. have purchased the Quebec Southern & South Shore Railway. The new company will spend a large sum in improvements and will compete actively in Southern Quebec with the Grand Trunk and Canadian Pacific.

Some of the firms who have recently placed orders with the Smart-Turner Machine Co., of Hamilton, for their standard duplex pump, include the Wilcox, Doolittle Co., the Port Hope Electric Light & Power Co., the Jenckes Machine Co. of Sherbrooke, the Hamilton Mountain Park Co., the Barrie Tanning Co., and the Marlatt & Armstrong Co.

The Alexander Brown Milling Co., Toronto, have taken out a permit for a flour mill to cost $40,000, to replace the one recently destroyed by fire.

Plans are being prepared for two business blocks to be erected at Fort William next year, to be erected by Messrs. Hitchcock & McGregor.

P. McCulloch, Hamilton, is to build two brick houses to cost $2,600; John Slater two more to cost $3,000, and Roy Isbestor one to cost $3,000.

The B. Greening Wire Co. have placed an order with the Smart-Turner Machine Co., Limited, Canada, for one of their single acting power pumps.

The Canada Cycle and Motor Company have started work on the erection of a brick building for manufacturing automobiles at Toronto Junction.

The C.P.R. is preparing to operate extensive coal fields near Hosmer, B.C. Owing to agreements productive work cannot be commenced until 1907.

W. A. Wilson, of the firm of Williams & Wilson, machinery merchants, has recovered from a severe attack of typhoid fever and is again at his business.

The Davis Tanning Co. propose to expend $50,000 in extending their plant if the city of Kingston will grant an exemption from taxation for twenty years.

Fire destroyed the car shop and blacksmith shop of the Prince Edward Island Railway at Charlottetown last Saturday, the damage amounting to $60,000.

The International Railway, Niagara Falls, has placed an order for 100 new cars to cost $600,000. The J. G. Brill Co., of Philadelphia, have secured the order.

Trim—Unless where otherwise specified, to be clear pine, spoon cleaned, and principal rooms to be for enamel finish (Harlequin ice cream)· a nice cream.

The Halifax Board of Trade is making vigorous efforts to secure Government assistance for the establishment of a steel ship building industry in Nova Scotia.

An electrical transmission line is to be constructed from Copper Cliff to the new Craighton mine, and a power house is to be erected for the electrical machinery.

F. B. Robins, has purchased 140 acres of land at Hamilton and proposes to dispose of part of it for manufacturing sites, and build residences on the remainder.

The open hearth steel furnace of the Dominion Iron & Steel Co. created a record one day last week, when the batter turned out 902 tons in twnety-four hours.

The Welland Board of Trade has endorsed the proposition that the town council purchase and operate an electric light plant and sell electric power to manufacturers.

A new nail works is to be established at St. John by Mr. Even Perkins, recently manager of the Maritime Nail Works, now controlled by the Capewell Horse Nail Co.

New Hampshire and Massachusetts capitalists have secured 30 square miles of timber lands in British Columbia, and will construct a large saw mill near Vancouver.

Ten tons of magnetic iron have been shipped to the "Soo" by the B. C. Mills, Timber & Trading Co. from its mines on Redonda Island, eighty miles from Vancouver.

The Canadian Pacific Railway Co. has spent $64,500 in building operations this year at Calgary. Large new freight sheds to cost $28,000 are also planned for construction.

Fire did damage to the extent of $5,000 in the premises of R. H. Buchanan & Co., machinery contractors, 234 Craig street, Montreal, in the early· morning of December 14 last.

The Dominion Iron & Steel Company has chartered the big Swedish steamer Drottning Sophia to engage in next season's iron ore trade from Wabana, Newfoundland.

A number of Montreal capitalists are applying for incorporation under the name of the Dominion Steel Car Co., Limited, to manufacture cars and all their component parts.

The Manitoba Iron Works, Limited, Winnipeg, have secured the contract for the new well caisson for that city. Heretofore these contracts have gone to eastern manufacturers.

London and Stratford capitalists propose to erect an abattoir near the city of London, providing certain privileges are given the company, which will be capitalized at $125,000.

Portage la Prairie is to vote on the question of granting inducement to the London Wire Fence & Machine Co., who propose to erect a $30,000 factory in the west end of the city.

The Peacock File Co. have definitely decided to locate in Welland. The company have $5,000 worth of machinery at Buffalo which they desire to bring into Canada free of duty.

A $50,000 steel and concrete bridge will be erected over the Bow River at Calgary, by the Alberta Government. A Normal School, to cost $60,000, will also be erected at Calgary.

The Le Roi amalgamation scheme is not to go through according to cable reports of a meeting of the shareholders at London, Eng., last week. The decision means much to Rossland.

The B. F. Sturtevant Co., Boston, been awarded the contract of heating and ventilating the large new factory of the Fairbanks-Morse Co., Toronto.

The Huron & Ontario Electric Railway, which has expended $100,000 in construction work is said to intend to open up a line next Summer from Walkerton to Meaford and Owen Sound.

W. K. Vanderbilt inspected the Ontario Power Company's plant at Niagara Falls this week, the New York Central having decided to electrify their railway lines in Western New York.

J. S. Stevenson, Pittsburgh, has placed an order for a steamship with triple expansion engines. It will be used on the Muskoka Lakes, and will be one of the finest ever turned out at Kingston.

Two by-laws have been carried at Winnipeg, one being to grant $150,000 to the hospital and the other authorizing the expenditure of $650,000 in building and equiping a municipal gas plant.

The Nova Scotia Steel & Coal Co is making preparation to open a new colliery at Sydney Mines, N.S. The company also intend to install an electrical plant to develop power for their mine.

The Grand Trunk Railway Co. have announced that they intend to spend $6,000,000 on a new station, to be erected in Montreal. The tracks are to be elevated and other improvements made.

Roofing — Material to be haunch of venison, made secure with good roofing composition of red current jelly. Watercress. To be rendered weatherproof by a thorough application of best mastic-(ation).

The Chapman Double Ball Bearing Co., Toronto, have received the contract for the equipment of the new plant of the Meaford Wheelbarrow Co., at Meaford, Ont., with their double ball bearings.

The report of the building done at Hamilton in the month of November shows a wonderful increase as compared with November last year. The figures are: November, 1905, $395,625; November, 1904, $68,200; an increase of $327,425.

Operations have commenced on the new factory of the Ingersoll Nut Co. Some of the machinery has not yet been installed, but the manufacture of cold punched nuts will be carried on from this time.

Canadian manufacturers are said to be inquiring in the English markets for supplies of steel strips for tube making, claiming that they are not able to obtain sufficient supplies of this material in America.

The Canadian Smelting Works at Trail has blown in its fourth copper furnace, this giving the plant a capacity of 1,000 tons of copper per day. The lead refinery is turning out 50 tons of pig lead daily.

The rail mill of the Dominion Iron & Steel Company is again in operation, having undergone temporary repairs. A new engine head, which has been ordered from Cleveland, Ohio, will be in Sydney in a few days.

Joisting—Bread and butter rolls. To be laid on bond timbers and properly bridged, and to be covered diagonally with butter (nut), knots less than 1½ inch allowed. Hair joints will not be required in this flooring.

The New York Central Railway has purchased the proposed new North Lanark Railway, which will have its starting point from Ottawa and the terminus at Madawaska, with branches to Arnprior and Fitzroy Harbor.

The Winnipeg Electric Power Company have constructed towers every 500 feet for the 62 miles between their power plant and Winnipeg. Another power company is installing a power plant on the Winnipeg River at Silver Falls.

The Eastern Coal Company, at Amherst, N.S., are to equip the mine with the most up-to-date machinery capable of turning out at least three to five hundred tons per day. There had already been upwards of 40,000 tons of coal taken out when the old slope was worked.

A new company is being organized to establish a carbide industry in Canada. Plants are to be erected at Fernie, B. C., and at certain points in Ontario and Quebec. The company will have a capital of $250,000, and it is expected the price of carbide will be reduced from $70 to $50 per ton.

Many mineral discoveries have been made in the Lake St. John district in Northern Quebec. Gold, copper, asbestos and nickel have all been discovered in considerable quantities, and a United States steel corporation has acquired several properties which they intend to develop later on.

Several industrial concerns are negotiating with the town of Fort William regarding establishing factories at that place. Amongst these are a wagon manufacturing company, a cast iron pipe foundry, a nail mill, large iron works for manufacture of bar and rod iron and a rolling mill for rails.

A copper smelter is to be established at Bruce Mines to treat the ores from the property recently purchased by the English syndicate. It is said that the syndicate will employ 500 men and endeavor to develop the Bruce Mines so that an output of 500 tons of copper per day will be possible.

Mr. Karnoch, chief engineer of the Canadian General Electric Co., Toronto, was inMontreal on December 12 to witness the testing of turbines supplied by his firm to the Canada Car Co., Limited. He was accompanied by Mr. F. C. Smallpiece, of the Peterborough engineering department of the same firm.

The Canada Cordage Flax Co., which has decided to locate at Glencoe, will expend $75,000 on building and machinery and will employ 90 men the first year. The town will submit a by-law guaranteeing the honds of the company to the amount of $40,000, provide a free site and give other advantages.

Thos. G. Anderson, formerly of Peterborough, has shown considerable enterprise in establishing the Hamilton Pattern Works, and is now located at 134 Bay street north, Hamilton, Ont. This firm make patterns for iron, steel and brass castings; metal patterns, and make a specialty of difficult core work.

The Atlantic Grind Stone, Coal and Railway Co's. properties near Amherst, N.S., are to be still further developed. A new reef of superior grind stone has been uncovered and additional machinery is being installed. New buildings and machinery have also been erected in order to increase the output of the coal mine.

The Chapman Double Ball Bearing Co., Toronto, report a steady increase in the demand for their goods, and state that a very large part of their bearings go to replace the old style, self-oiling journal bearings, which have been discarded, owing to the heavy loss of power which is caused by these journal bearings.

The Montreal Builders' Exchange had a right good time at the banquet held recently the success of which was largely due to the efforts of President N. T. Gagnon and Vice-President E. M. Roberts. The feature of the evening was a most cleverly prepared menu card, entitled "Specifications."

Heintzman & Co., Toronto, have purchased a site on Yonge street, where McDonald & Willson's stove store now stands, and will erect a ten-storey building, which they will use as piano warerooms. The site cost $120,000, being at the rate of $3,000 per foot. McDonald & Willson have the right to remain in their present store for three years longer.

The Volta Electric Co., finding their premises too small to take care of a growing business, have moved from 86 to 88 Adelaide street west, Toronto. A new front is being put in the premises, and bright and attractive quarters will be the result. Hitherto their office was overhead, but it is possible with the new arrangments to have the office on the ground floor.

W. H. Banfield & Sons, Adelaide street west, Toronto, are about to more than double the capacity of their plant. A rapidly growing business has necessitated this. At the rear of the present works a two-storey addition has been made and the machinery installed therein. This latest move should give the firm of Banfield & Sons a better opportunity to keep up with their numerous orders.

The rise in lead has been so marked as to stop payments of the bounty given by the Dominion Government. It was paid on a sliding scale, which reduced the bounty as the price rose. Just now the price is so high that the bounty is nil. As salmon canners have to make preparation almost a year in advance for their supplies of lead, tin and tin plate, the belated ones are hit hard by the high prices.

Within the past two months Allis-Chalmers-Bullock, Limited, have made contracts for the electrical equipment of the Keewatin Flour Mills Co., Keewatin; the Ogilvie Flour Mills Co., Fort William, and the Western Canada Flour Mills Co., St. Boniface, aggregating 4,000 h.p. The motors range from 500 h.p. downwards. The entire equipment is under construction at the shops in Montreal.

The first of two lunch rooms, each to accommodate 350 men at a sitting, has just been opened at the Angus shops of the Canadian Pacific Railway. It is the intention to provide meals at bare cost price, or to heat up food which the men may bring from home. As there are between four and five thousand men employed at these shops, the seating capacity is expected to be taxed to its utmost capacity.

The C.P.R. has announced its plans for railway construction on Vancouver Island for next year. The extension of the E. & N. Railway, now owned by the C.P.R., through Comox to Campbell River, near the north end of the island, is proposed, and a branch from Duncan's via the Cowichan Valley to Alberni on the west coast of the island is another extension for which power to construct will be sought.

There are now fifteen members on the Granby board of directors, those newly elected being George Crawford Clark, Sanford H. Steel, and Edwin Thorne. Application has been made to the Legislative Assembly of British Columbia to change the par value of the stock from $10 to $100 a share, thus reducing the number of shares. A dividend of 3 per cent. has been declared on the capital stock out of the net earnings.

The machine room of the Piedmont Paper Co., Piedmont, N.Y., containing over half a million cubic feet of space, is to be ventilated by apparatus furnished by B. F. Sturtevant Co., Boston, Mass. This will consist of an engine-driven fan with heater, and a system of distributing pipe which permits of so discharging the warm air as to instantly absorb the moisture in the atmosphere and keep it perfectly clear.

The Collingwood Shipbuilding Co. has closed contract for the construction of two steel steamers. The contract price for the two is about $400,000. One is to be built for James Playfair, Midland, being 486 feet in length and having a carrying capacity of 323,000 bushels of wheat. The other is for the Montreal Transportation Co., it being for a barge 206 feet in length. About 700 men will be employed building the boats.

The town council of Westmount, P.Q., is considering a new building by-law which, if it goes into effect, will make it unlawful for any person to build, have or maintain any dwelling house which occupies more than two-thirds of the building lot on which it is erected, to construct in such building any sleeping room which is less than 640 cubic feet in dimension, and which does not possess direct communication by window with the out-of-doors.

Toronto capitalists have acquired the Brantford Street Railway, the Grand Valley Railway between Paris and Brantford, and the Woodstock, Thames Valley & Ingersoll Railway running between Woodstock and Ingersoll. Among those interested in the purchase are A. J. Pattison, W. S. Dinnick and John Firstbrook. Some of the stock will still be retained by people in Brantford. The roads will be greatly improved and the lines extended.

Crawford Bay, on Kootenay Lake, the site of a former smelter proposition, is to be the scene of activity in the first development of the iron industry in the interior of B.C. A syndicate of Cleveland, Ohio, capitalists, headed by Matthias Horsling, has bought the iron mines owned by Nelson people, in that vicinity and a plant is to be built next Spring. A mono-rail road is to be laid for carrying the ore to Crawford Bay from the mines.

An alliance of great benefit to the "Soo" industries has been formed between the Lake Superior Corporation and the Canadian Pacific Railway. The big railway is now getting over $100,000 a month for hauling the business of the different subsidiary companies of the Lake Superior Corporation. In return, the Canadian Pacific has become the largest and one of the most profitable

eustomers of the steel rail mill of the Algoma Steel Company.

The Great Northern Railway has issued a new lumber tariff effective on the new branch line to Fernie and on the Nelson-Waneta branch to Winnipeg and and a number of other Manitoba towns. The new rate is 33 cents per hundr?d, a saving of between 60c and $1 per foot over the old rates. Formerly the trade from the Nelson branch paid a 5-cent local rate to Nelson, and the C.P.R. carried the lumber east from that point at its regular tariff.

The Stuart Machinery Co., of Winnipeg, have suffered the destruction of about twenty-five feet of their machine shop by fire recently. Although considerably hampered they resumed work shortly after. The damage consists chiefly through the repair shop, where they had a large number of parts of engines in for repairs, which will be hard to replace. A number of motors and armatures stored above the machine shop were also totally destroyed.

The report of the building inspector of Montreal as to building operations in the city and vicinity shows that seventy-seven permits for new buildings were issued during the month of November, the cost of the structures being $313,645. Permits for alterations numbered twenty and involved an amount of $26,871. This made a total amount invested in building operations last month of $340,576, an increase over the corresponding month of last year of $105,611.

Coal shipments to the St. Lawrence from Cape Breton this year are the largest on record, 1,121,008 tons having been shipped by the Dominion Coal Company alone from Sydney. A few years ago the entire Cape Breton output was little more than this. It is expected that the Dominion Coal Company's output for the year will amount to well over three million tons, while the output from the other mines will hring the Cape Breton total up to 4,000,000.

Vancouver City Council proposes submitting money by-laws to the ratepayers at the coming civic elections, for works and improvements totalling nearly a million dollars. The chief item is that providing for waterworks extension, including the establishment of a high level service, which means practically a new system. This will cost $750,000, and construction will cover three years. The other hy-laws are for schools, sewers and streets. In 1905 money by-laws totalling some $600,000 were voted on and carried.

The British Columbia Telephone Co., operating plants in all the chief cities of the province, announce the immediate construction of a fine three-storey brick block in this city, to be used as a central office. In this a modern switchboard of large capacity is to be installed, the cost heing estimated at over $100,000 for the switchhoard alone. The first installation will be for 4,000 pairs of direct wires, while with addition of sections the capacity can be raised to accommodate from 13,000 to 14,000 subscribers.

Another new industry that will give employment to a large number of hands is now being estahlished in Vancouver, and will be in full running order in a few weeks. At an expenditure of nearly $50,000 a new can factory and sheet metal works is being installed bv the A. M. Forbes Hardware Company in a large new factory on Seymour street, which is now receiving its finishing touches. The factory is a commodious four-storey frame building, located on the west side of Seymour street.

The Standard Bolt & Serew Co. has fitted up a large plant at the corner of Sorauren avenue and Dundas street, Toronto. The equipment is entirely new and up-to-date in every partieular. This firm intends manufaeturing on a large seale bolts of all kinds, ineluding carriage, railroad traek bolts, nuts, cap screws, set screws, studs, ete. The proeess of manufaeture is well under way. A new building is being erected nearby for the manufacture of drop forgings, a line this firm intends to go into on a large scale.

It is understood that the Grand Trunk has let the contract for the equipment of the Port Huron-Sarnia tunnel with electrie power for the operation of trains. The contract involves the building of large power houses in Port Huron and Sarnia, and the total eost is said to be nearly $700,000. The third rail system and powerful eleetric locomotives will be used. The adoption of eleetricity will remove all danger from gas in the tunnel. The eompany has been working on plans for this improvement for three years.

New Westminster is not satisfied with merely recovering her long lost prestige as a deep-sea port, which was effected this month by the arrival of the British ship Wethersfield to load lumber at the Fraser River Saw Mills, some miles above the city: The Roval City now seeks to establish a ship-building industry, the object being to secure Dominion aid hy way of honus per ton on all steel ships constructed there. The appeal of the Halifax Board of Trade for endorsation of their petition to the same effect, set the Royal citizens thinking.

The 30-stall roundhouse of the Intercolonial Railway, Truro, N.S., is being equipped by the B. F. Sturtevant Co., Boston, Mass., with a complete heating and ventilating system especially designed for the rapid thawing out of engines. An induced draft apparatus is also being furnished for the boiler plant.

The St. Denis boulevard ear barns of the Montreal Street Railwav Co. are being equipped by the B. F. Sturtevant Co., Boston, Mass., with two complete heating apparatus and an indueed draft apparatus for the boiler plant.

Owing to the increase of business and the growing importance of Montreal as a centre for distribution of their products, the Robb Engineering Co., Amherst, N.S., have decided to change their agency at Montreal into a branch office. Mr Watson Jack has been appointed manager, and Mr. Allister McLean will continue in the capacity of engineer for the Montreal district. The Robb Engineering Co. will have their quarters in the suite of offices occupied by Messrs. Watson Jack & Co., in the Bell Telephone building, corner of Notre Dame and St. John street.

The C.P.R. have decided to relay with new steel next year the entire Crow's Nest Pass line from Lethbridge to Kootenay Landing, a distance of 211 miles. The total contemplated improvements will cost $1,250,000. Each mile will take about 125 tons of rails, or say 26,375 tons for the entire distance. Each ton of rails will cost (exclusive of freight) $33, or $869,275. Labor will eost about $120,000, and the ballasting of the road for the new rails will mean an outlay of $211,000. Extra expenses of one kind or another will exhaust the appropriation of $1,250,000.

Across the inlet from Vancouver a new eity is soon to be born. The North Vancouver rural district is to be divided, and the portion on the waterfront, already being developed as a townsite, is to secure civic life. The expected advent of a railway will give impulse to the city now in process of organization. An agreement has been made with the municipality as it now exists for the installation of street car lines. Some six miles are to be constructed early in the Spring, plans for the work having beens approved by both the municipality and the B. C. Electric Railway Company.

By the success of A. J. McMillan, formerly managing director of the Le Roi mine at Rossland, in being returned to office after having been voted out at a previous meeting of the directors in London, marked changes are to take place at the mining city. The Le Roi is to be deepened and the ore which has been of late going to the big C. P. R. smelter at Trail is to be shipped to the Le Roi's smelter at Northport. Wash., which has of late been shut down. This smelter is owned by the Le Roi Company, and is located just across the international boundary in the State of Washington.

The ground floor of the new factory will be devoted to one of the largest tin and sheet metal works in the province, giving steady employment to about twenty-five hands. The second floor will be devoted to a corniee and roofing establishment, also employing a considerable number of hands, while the can factorv, when in full swing on the large orders which the firm has already booked, will give employment to about fiftv skilled eanmakers. Altogether nearlv a hundred men will be engaged in this new industry. This factory is an entirely separate institution from the firm's business on Hastings street.

Among recent contracts for heating and ventilating equipment placed with the B. F. Sturtevant Co., Boston, Mass., are included those for the National Tube Co., McKeesport, Pa., for rolling mills and machine shop, containing over 1,000,000 cubic feet of space; for the Fairbanks-Morse Canadian Mfg. Co., Toronto, Ont., including separate apparatus for machine shop, blacksmith shop and foundry; for Brown & Sharpe Mfg. Co., Providenee, R.I.; for Pressed Steel Car Co., Mc Kee's Rocks, Pa., for ear paint shop containing nearly 4,000,000 eubic feet of space; and for a similar shop containing over 2,500,000 cubic feet at the Allegheny, Pa., plant of the same company.

With another month yet to run, the cost of building operations in Winnipeg

this year is within a quarter of a million of the $10,000,000 mark. The number of permits and the value of buildings for which permits were given during the month of November greatly exceed the figures of the same month last year. Following are the statistics: Value of buildings, January 1 to November 30, 1904, $5,640,110; 1905, $9,743,560. Value of buildings for month of November, 1904, $471,590; 1905, $788,771. Number of building permits issued January 1 to November 30, 1904, 1,742; 1905, 2,569. Number of buildings for which permits were issued for month of November, 1904, 156; 1905, 238. Number of new buildings erected from January 1 to November 30, 1904, 1,620; 1905, 2,933.

Following the annual meeting of the Pacific Coast Lumbermen's Association, held at Tacoma on Tuesday, 12th inst., it is announced that a decision had been reached to raise the price of lumber to a $13 base, to go into effect at once, and to prepare a list on a base of $15, to be effective February 1. This will chiefly affect export cargo trade, but it is noticeable that in local circles the rumor is current that a meeting of the local association is likely to be called ere long to discuss prices for local consumption as well as for export east. The shortage of logs at this season is having some effect on lumber conditions. Another point is brought up, that the continuation of the boycott by local merchants will have the effect of making a car shortage which will adversely reflect on the lumber trade.

There is talk of the starting of a steel rail mill in the Kootenay district of British Columbia. It is said that the iron mines, owned by G. B. McMillan and R. Robinson, of Nelson, on Crawford Creek, have been sold to a syndicate of Cleveland and St. Paul capitalists, headed by Matthias Horsling of Cleveland. The purchase price is in the neighborhood of $75,000, and the new owners will begin active operations on June 1 next. Their plans include the construction of a mono-rail line from the mines to Crawford Bay. The new properties will be operated in connection with steel works already in existence, either at the coast or in the east. The company propose to expend $150,000 next Summer in putting in rolls, and providing transportation facilities between the mines and the lake shore.

Conditions which are rapidly driving large manufacturing interests from the United States to Canada are to be considered within a few days by the Illinois Manufacturers' Association. Reports just gathered show that 132 of the leading concerns of the country have been obliged, chiefly on account to tariff restriction, to establish branch plants in Canada. The resulting loss financially is estimated at upwards of $50,000,000. The agitation which the Illinois manufacturers are about to start is expected to assume the form of a national appeal to Congress. The remedy most in favor locally and throughout the country provides for reciprocity legislation which will permit of a freer exchange of American and Canadian manufactured products. It is likely that Congress will be asked during the present Session to take some steps in this direction.

Canada's imports reach the total of $251,603,000, or twenty-five per cent. of the United States' total imports. Canada, with one-fourteenth of the population of the United States, is only quadrupled by that country in the value and volume of her imports. For every $2.50 worth of imported goods consumed in Canada, 70 cents' worth of imported goods are consumed in the United States. The meaning of this difference is that Canada should manufacture more and import less. Canada is not superior to the United States as a consumer of goods, domestic or manufactured. The United States is superior to Canada in manufacturing to supply her own needs instead of having to import. Canada should increase her manufactures and decrease her importations, especially at the expense of the United States, which supplied $152,431,626 of our importations, or 60.58 of the total.

One measure of the development and peopling of the northwest may be found in the erection there of flour mills to meet the local as well as the export demand for flour. The Western Canada Flour Mills Co., which has already a mill at Brandon as well as at Goderich, is now erecting another of the great capacity of 4,000 barrels per day at Winnipeg. In order to have their flour mill up-to-date in every particular, the company will operate by electricity, and has just awarded the contract for the necessary equipment to Allis-Chalmers-Bullock, Limited, of Montreal. This contract includes two synchronous motors of 500 horse power capacity each, and a number of smaller motors, which, ranging from 5 h.p. to 200 h.p., aggregate 750 h.p. It also includes switchboards, transformers and accessories. The mill, which was designed by Mr. R. J. Megaw, will be of the most modern type and the electric equipment necessary makes one of the largest orders for this class of work ever given in America.

The Westinghouse Electrical & Mfg. Co. are furnishing equipments for an unusually large number of industrial power plants of a diversified character. Owing to the magnitude of the works of the Westinghouse Electric & Mfg. Co., at Pittsburgh, a great many people have received an erroneous impression that the product of this company consisted principally of only the larger types of electrical apparatus, especially so with reference to electrical generating units. This wrong impression is largely due to the fact that many of the great power plants of the country, having the largest units, are equipped with Westinghouse generators and auxiliary apparatus. The aggregate business of this company, however, in the smaller units, far exceeds that of the larger and special types. They manufacture every kind of electrical apparatus for either light or heavy work, and their instruments for measuring electrical energy equal in delicate construction the works of the better class of modern watches. These instruments are recognized standards in their field.

The Montreal Street Railway Co., Montreal, have awarded the contract for their new car barns to the Canadian White Co., Montreal. Each of the sheds will be 202 feet long, 140 feet wide, and 17 feet 4 inches high, from top of floor to underside of beam, each having a capacity of 48 cars, 50 feet long over all. The foundations will be of concrete. The walls and piers are also to be of concrete, with foundation bolts built in them. The walls of the buildings are to be of sound, plastic, hard-burned brick. The floors will be nine inches concrete laid on the levelled surface of the ground pitched to gutters, with a finishing layer one inch thick trowelled to a smooth and level surface. The construction of the iron work will be all riveted; load assumed for roof being 75 pounds. The doors will be adapted to the requirements of a street railway, and operated by hand. The heating will be by the fan system of hot air, and of a capacity to change the air four times an hour and to heat the building to 70 degrees F. in zero weather. Steam will be furnished by two horizontal tubular boilers and furnished with induced draft fans. A feature in connection with these new sheds will be that the flooring between the tracks in the front part of the sheds will be lowered 18 inches below level of rail, to facilitate the examination of trucks, etc., without jacking up of cars.

Cement Mill May Move.

The next meeting of the National Portland Cement Company's shareholders promises to be an interesting one. The directors of the company have recommended the removal of the company's mill from Durham, Ont., on account of the scarcity of raw material in that locality. The town council of Durham disputes the statement that material is scarce, and a committee appointed by it, under the chairmanship of Dr. Jamieson, M.P.P., investigated the question, and reports that there is a sufficient quantity of marl obtainable to keep a cement mill running for a man's lifetime.

The company was capitalized at one million dollars, a quarter of a million of which went to the promoters. A mill was constructed with a capacity of 1,000 barrels a day, and said to be one of the best mills on the continent. In the building of it, however, a liability was incurred, which was increased by inexperience of workmen and accidents during the first year. No dividends being forthcoming, the stock fell to 16 cents on the dollar.

This last year things went very much better, and the company was enabled to pay back $13,000 which had been borrowed from the bank, and to reduce the indebtedness from $127,000 to $30,000. On the ton of this favorable report the citizens of Durham, who are largely interested in the company, were thrown into consternation by the resolution of the directors to move the plant elsewhere.

Economy in Steam Power.

On this subject Professor R. J. Durley, of McGill University, read a very interesting paper before the Canadian Railway Club at their last monthly meeting.

In the course of his remarks Professor Durley said that although there is a great future before the gas engine as a source of power, the time has not quite arrived when it can be looked upon as a commercial competitor with the steam engine or turbine, under any but exceptional circumstances. At the present time a producer gas plant for anthra-

cite coal, with gas engines and generators, will cost in Canada about 20 per cent. more than a steam plant to take the same peak load. The cost for fuel at high load factors is considerably less for the gas plant, but this saving is much smaller at low load factors, on account of the higher fixed charges.

Dealing with engine room costs, Prof. Durley claimed that engineers on this side of the Atlantic had been somewhat slow to realize the very excellent results which had been and were being obtained in Europe from the use of superheated steam. The installation of heaters was, however, coming more and more into favor in Canada.

In conclusion the speaker referred to the cost of labor in the engine room. This depends, he said, not only on the type of motive power adopted, but also very largely on the arrangement of the machinery in the engine room, and especially on the amount and complexity of the auxiliary machinery installed.

Ontario Mining Conference.

An important event in the annals of mining development in Ontario took place in Toronto, Tuesday to Friday, December 12 to 15, when delegates from the different mining centres of the province met in conference at the Parliament buildings at the instigation of the Government. Mr. W. D. McPherson, K. C., was elected chairman and presided at the different meetings. At the first meeting the subject of royalty was discussed and a resolution opposing the paying of any royalty was unanimously adopted. Another resolution carried was "that there should be only one mining law for the whole of the province." Prospectors' rights were discussed and a resolution that carried unanimously passed to the effect that prospectors were to be given a title to claims discovered in timber limits, after which the owner of such limit was to be given three years to remove the timber therefrom. Recording districts were deemed advisable and a resolution to this effect adopted. All Wednesday morning and most of the afternoon was taken up with a debate on the resolution: "That any licensee may stake out a location without first making a discovery of mineral thereon." The prolonged discussion ended in the amendment as follows: "That any licensee may stake out a location without first making a discovery of mineral thereon under stringent working conditions to be decided by the meeting." Other resolutions carried were: "That all locations shall be recorded within fifteen days after staking, if within ten miles from recording office, one day additional being allowed for each additional five miles." "That during the period between staking and recording the claim the licensee first staking shall be entitled to full possession and preservation of his rights." "That locations shall consist of 40 acres except in cases of fractional locations. In surveyed territory locations should consist of a fractional part of a lot." The situation regarding the mining claims on the Gillies timber limits was reviewed on Thursday, but the resolutions and amendments thereon were considered unsatisfactory. It was generally admitted that this would be the most difficult question with which the Government will have to deal. Resolutions passed were: "That the Department of Lands and Mines be divided into two departments, one to be known as the Crown Lands Department, the other as the Department of Mines, each with a minister at its head. That all mining partnerships be recorded in the recording office in which the mining claim is registered, and a simple method for the registration, dissolution and enforcement of other rights of the partnership be provided. That the Ontario Government grant to the ore-producer a bounty for the production of pig iron by Ontario furnaces when such iron is made wholly from Ontario ores. That although it is desirable that assistance be given by the Dominion Government in the way of bounties on pig iron smelted in the Dominion, the convention protests against the present system of bounties on iron smelted from foreign ores, and asks that the same be discontinued when the present law expires in June, 1907, but that the bounty on pig iron made from domestic ore be placed at $3 per ton for the next five years. That the Province of Ontario should erect a smelter and refinery capable of refining the silver-cohalt ores, and should make provision for refining the copper and nickel ores of the province. That the Dominion Government be recommended to admit coal free of duty, if used to make coke to be used for the smelting or treatment of iron ore. That the price of mining lands throughout the province be uniform, namely, $2.50 per acre in surveyed and $2 in unsurveyed territory. That a license be required to expend $100 in actual mining work during 90 days succeeding his application, excluding from the computation November, December, January, February, March, April, and a similar amount during three succeeding years, or prior thereto, such expenditure to be computed at the rate of $3 for each day's work performed by a grown man. Affidavit of expenditure to be filed with the recorder within 30 days after the time allowed for each expenditure. For every adjoining five locations or less held by one or more licensees and which are principally valuable for base metals, all such development operations may be carried on upon one or more of the locations." On Friday resolutions were adopted as follows: "That it would be advisable for the Ontario legislature to offer prizes for the demonstration of satisfactory methods for the treatment of refractory ores. That the Government should procure expert evidence as to the advisability of fully testing the Thunder Bay silver district. That an applicant for a mining location shall at the expiration of the time for his development work file with the recorder at least two affidavits of practical miners that he has complied with the regulations, otherwise the claims shall be considered abandoned. That the law giving township councils ownership of mineral on concession and side lines be abolished, and the mineral thereon being bargained for direct with the Crown Lands Department, the same title to be issued as is issued for the adjoining land. No licensee shall stake out or apply for more than two mining locations principally valuable for precious metals, or more than four locations principally valuable for base metals, within a radius of six miles thereof during any one calendar year, either in his own name or in the name of any other licensee." In the afternoon a deputation waited on Hon. Mr. Cochrane, Minister of Lands and Mines, and presented to him the resolutions adopted by the conference.

PERSONAL MENTION.

The death occurred very suddenly recently of Mr. J. B. Jackson, for many years registrar of copyrights and trade marks in the Department of Agriculture. Owing to his broad technical knowledge and long experience, Mr. Jackson was admirably fitted for this position and his loss will be keenly felt in the department. He was 59 years of age and leaves a widow, one son and three daughters.

* * *

A prominent mining capitalist and expert on mining affairs, Mr. Geo. G. Blackwell, of Liverpool, Eng., has recently completed a somewhat extensive tour of Canada and the United States. Mr. Blackwell thinks that mineral prospects in Canada are very gratifying, but is of the opinion that at present there is lack of capital in the Dominion to work the mines. He is satisfied that if Englishmen were ready to invest their capital in the Canadian mines the result could not help being profitable in every

The Oldest Working Grinder.

A representative of Canadian Machinery, while recently going through the works of George Butler & Co., Sheffield, England, noticed an old man at work despite his 83 years of age. The old fellow, James Sadler by name, commenced razor grinding when 13 years of age, and is still hale and hearty enough to spend four or five hours daily at his favorite work, three sons, one being 58 years old, assisting him at his wheel.

When he first entered the cutlery trade Sadler worked for Sir Frederick Thorpe Mappin, and went to Messrs. George Butler & Co. some 30 years ago, working there ever since. As may be guessed, he has ground thousands and thousands of razors in his time. When he gets into a reminiscent mood he has some interesting tales to tell. The great Sheffield flood is very fresh in his memory, and on that disastrous occasion he saw a stable full of dead bodies. The trades outrages, too, are well remembered by this veteran, and he was personally acquainted with most of the men who were punished for the despicable deeds they committed. In his younger days Sadler traveled by the old stage coaches, and he is one of those veterans who can boast of having journeyed in this manner as well as by water and rail. When he was 80 years of age a few of his friends entertained him to supper and presented him with a walking stick.

* * *

Climbing the Ladder.

In keeping with the general spirit of United States firms in recognizing Canadian ability and worth, the Wagner Electric Manufacturing Company has appointed Mr. G. Percy Cole, B.Sc., to the position of assistant chief engineer. Mr. Cole is a Montreal boy and an honor graduate of McGill University. That his success is well merited is the unanimous opinion of his many friends in this country.

Niagara's Future.

Monsignor Laflamme, the Quebec geologist appointed by the Dominion Government to investigate the geological conditions at Niagara, has recently placed on record his report to the Government. It is more or less a compilation of what has been already known on the subject. He assures Canada that as far as the action from natural causes is concerned this country will be the gainer, the future pointing towards the entire elimination of the American cataract. As a prophecy and a forecast of the future this report is interesting, but what is forecasted will not affect the present generation, nor possibly many succeeding ones.

New York and Brooklyn report 52 per cent. more construction in 1905 than in the corresponding period of 1904. Buffalo, 4 per cent. ; Chicago and Cincinnati, 60 per cent. ; Columbus, 65 per cent. ; Denver, 50 per cent. ; Detroit, 56 per cent. ; Indianapolis, 41 per cent. ; Kansas City, 27 per cent. ; Louisville, 76 per cent. ; Memphis, 29 per cent. ; Milwaukee, 28 per cent. ; Minneapolis, 35 per cent. ; New Orleans, 9 per cent. ; Omaha 69, Philadelphia 19, Pittsburg 49, San Francisco 30, St. Paul 80, St. Louis 88, Tacoma 4, and Washington 77 per cent. These reports are so favorable that they seem exaggerated, but there cannot be much doubt that they are approximately correct.

Ask for Catalogue J.

The "BORDEN" Machines are constructed entirely of Malleable Iron and Steel

M. E. MURRAY

CANADIAN DEALER IN
"THE BORDEN"
Pipe Threading Machinery and "Solid-Adjustable" Dies
16 Sheppard St., TORONTO, CAN.

METHOD
has much to do with the success of
"Bliss" Presses and Dies

Our method is to aim at the highest standard of quality, to use the best method of making by using jigs and the most improved machinery, and a method of inspection which prevents imperfect goods from leaving our shop. Large stock. Quality guaranteed. Prices right.

E. W. BLISS CO., 20 Adams Street, Brooklyn, N.Y., U.S.A.

EUROPEAN OFFICE—Clichy pres Paris, France. Distributing Agents for Chicago and vicinity—Stiles-Morse Co., 65 W. Washington St., Chicago, Ill.

MACHINERY BUYERS' DIRECTORY.

Readers of CANADIAN MACHINERY are invited to use this directory as a ready reference when seeking to buy any machinery or machinists' supplies. In it will be found a list of goods made by leading Canadian firms and by the principa firms in other countries who are devoting especial attention to the Canadian market. It is the intention of the publishers of this paper to issue a desk index for machinery buyers, and all advertisers are invited to send in full list of lines manufactured.

Abrasive Materials.

Canada Machinery Agency, Montreal.

CONDENSED MACHINERY ADVERTISEMENTS.

Rates—25c. for twenty words or less; 1c. a word for each additional word.

AGENTS WANTED.

WANTED — Practical machinists, to act as representatives of CANADIAN MACHINERY in the shops they work in; liberal commission offered. Address Business Manager, CANADIAN MACHINERY.

FACTORY FOR LEASE.

MANUFACTURERS — An Eastern Ontario town is in a position to offer to a desirable manufacturing concern a factory, fitted for metal working, wood working, or both, at lease merely sufficient to cover insurance; no taxes except school rates; site near railway, with switches to every part and with river at door. Apply CANADIAN MACHINERY, Toronto.

MACHINERY FOR SALE.

FOR SALE—One 3-phase, General Electric Co. of Sweden, generator; 100 k.w., 500 v., 60 cyc., 7,200 alt.; complete with exciter and switchboard, on which are mounted volt meter and amin meter. Apply Sandford Furniture & Woodenware, Limited, Fenelon Falls, Ont. (3x)

FOR SALE—65 h.p. boiler and engine—also 50-barrel roller and grist mill, with or without machinery; building suitable for any manufacturing purpose, woolen or knitting mill; good opening for box, sash and door, planing mill, etc. For further particulars, apply W. F. Lewis, Grimsby.

POWER STAMPING MACHINE and punch, for ⅜ metal; nearly new, and large quantity of refined English steel wire, from 16½ to 23, and heavier sizes; for sale at a bargain if bought soon, to clear out. Brown & Co., Paris.

FOR SALE—Cheap—2 forty h.p. boilers, with stack; National feed water heater; sawmill carriage, with iron saw frame; friction feed; solid saws; grain grinder. For price, write J. S. Findlay, Owen Sound.

AD.-WRITER WANTED.

WANTED—A strong, steady, preferably experienced writer to look after the publicity end of wholesale and retail concern. Good salary. Apply by letter only. Advertiser, care of Manager, MacLean Publishing Co., Toronto.

MACHINERY WANTED.

WANTED—Second-hand Planer—double surfacer and matcher; must be cheap. D. Clarke, Powassan, Ont.

WANTED—Pole tool well-drilling machine; state price. F. McCann, Box 737, Owen Sound, Ont.

SADLER & HAWORTH

The **Best Selected Steer Hides, Tanned** by **Oak Tanning** make the **Leather** that **makes SADLER & HAWORTH BELTING.**

Through thirty years of practical **Belt Making**, we have found out all the "whys" and "wherefores."

It is to our interest to make **Good Belting,** and we do it.

We do not want you to buy only **One Belt.** We want to supply you with **All Your Belting.**

Our **Grades** will always be found to be **Uniform in Quality.**

We aim to make **Our Belts** a little better than the best. A trial order will convince you that **We Have Succeeded.**

Offices and **Factories** at **MONTREAL** and **TORONTO.**

H. Steel Castings

Expert Cracksmen have failed to break H. Steel Castings.

Scientists and Machinists have branded H. Steel as perfect steel.

Made in any size and to suit any purpose. Absolutely free from blow holes.

Will last longer than any other casting. Sound to the core.

We make **MILL MACHINERY, CASTINGS** and **MACHINERY** of all descriptions.

A specialty is made of H. Steel, because the patent is ours and it can be had only from the

OTTAWA STEEL CASTING CO.
OTTAWA, ONT. LIMITED

ALPHA
HIGH-SPEED STEEL

holds an edge longer and cuts faster and deeper than other steels; besides, it stands under heavier cuts and coarser feeds.

ALPHA HIGH-SPEED STEEL

is just what every Machine Shop requires and should get. For Lathe Tools, Milling Cutters, Drills, Taps, etc., it is ideal.

Write for full particulars.

SYLVESTER GASOLINE ENGINES

ARE THE BEST SKILLED LABOR CAN PROVIDE

They are easy starting; they are simple and reliable; they will give full power in the coldest weather; they are built in sizes from 1½ to 32 horse power; they will run on gasoline, coal oil or distillates.

The SYLVESTER Engine inspires confidence because it is so simple in construction. It is the cheapest engine to buy because there is nothing to get out of order.

STARRETT TOOLS

ARE THE STANDARD

FOR ACCURACY, WORKMANSHIP, DESIGN AND FINISH

Improved Levels for Testing Shafting, Etc.

In addition to the regular parallel vial, the bases have a cross level which enables one to place or hold the base on a shaft level in its cross section, not canted sidewise; for the shape of a level glass is such that, though true as adjusted on a flat surface, it will not be reliable when canted sidewise. Hence the value of the cross level, not only to test the truth of shafting, but other surfaces which tend to throw the level base into a canting position.

The base of this level has our improved concaved groove running through the length of its base, leaving a flat margin each side, which improves its seat for flat work, while forming an absolutely true and reliable seat for shafting, etc., and is better than a V groove. Made in 6, 8, 12 and 18 in. sizes with plain vials and with ground and graduated vials.

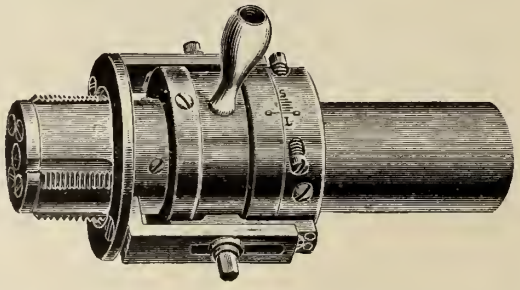
ADJUSTABLE COLLAPSING TAPS



The **GEOMETRIC ADJUSTABLE COLLAPSING TAPS** have beaten the old solid taps to a stand-still and continue to roll up new records.

Are designed for use on the turrets of hand or automatic screw machines, or can be rotated on live spindles.

If you have accurate tapping to do on duplicate work, these tools are indispensable—they not only do better work, but will do it in at least one-half the time formerly required.

Have adjustable, interchangeable, quick opening and closing chasers, and are made to tap pipe from 1″ to 12″ diameters, inclusive.

Let us have a sample of your work and we will furnish specifications and prices on a suitable equipment to cover same.

Absolutely the most rapid means of tapping duplicate parts.

Give us a chance and we will help you lessen your production cost.

THE TECHNICAL PUBLISHING CO., LIMITED, 287 Deansgate, Manchester, and all Booksellers.

ABSORB THESE FACTS

We want every manufacturer, every machinery dealer, every mechanical expert, every machinist in Canada and every machinery manufacturer in the world to KNOW the facts below. Don't merely glance at them; understand what they mean.

I. Canada has become one of the industrial countries of the world: in proportion to its population it probably uses as much machinery and power equipment as any country.

II. Canadians are interested in their country, are intelligent and progressive; consequently they read—carefully, as a rule—CANADIAN MACHINERY AND MANUFACTURING NEWS in order to keep up-to-date.

III. CANADIAN MACHINERY is the largest as well as the most practical and most comprehensive mechanical paper in Canada. Its connection with advertisers is made apparent by an examination of its pages; its connection with readers is even more comprehensive—our subscription lists are open for examination at any time.

IV. If you want to sell machinery or power equipment you must reach the man whose technical knowledge is such that he can appreciate your arguments and so that his opinion will carry weight; in short, you must reach the practical men—CANADIAN MACHINERY is essentially a paper for the practical man.

If you want to get connection, if you want to sell machinery or power equipment of any kind, you should advertise in CANADIAN MACHINERY—the largest, the most practical mechanical paper in Canada.

It pays every reader of CANADIAN MACHINERY to read every advertisement thoroughly. Answer such advertisements as interest you and insist on getting all information possible about all machinery or power equipment such as you might use. It pays to keep posted.

The Lever You Want Right At Your Finger-Tips

Stop running "round" to the back of your machine for a lever that you use from 1 to 20 times a day.

Everything Within Easy Reach of the Operator

This is what we claim for this new 30″ **BICKFORD RADIAL**—in fact for all our Radials. And we can prove it, too, not by argument or glib assertion, but by actual demonstration. Look at the cut—did you ever see a handier, neater or more stockily built Radial in your life?

And it's just the thing for taking care of the ordinary work as found in the average shop—it was built for that purpose, you know.

Then, again, we want you to put in the little Radial in place of the large Upright you were thinking of buying. It doesn't cost much more, has infinitely greater productive capacity and will out-last and out-drill any Upright ever built.

It's made in three lengths of arms, remember, 30″, 36″ and 42″.

Circular 1-A. Shall we send it?

"CINCINNATI" HEAVY DUTY SHAPERS

Are built to stand the excessive strains caused by heavy cuts and big feeds with high-speed steels. All sliding bearings have taper gibs, adjustable endwise by single screws, and the crank block is drop forged. A high-gear ratio, an ample amount of cast-iron properly distributed, and high-class workmanship, combine to place the "CINCINNATI" in the front rank.

OUR WET TOOL GRINDER
Is Always Ready for Use.

Absolutely nothing to get out of order or in any way give trouble.
Well constructed and easy to operate.
A very practical, efficient and durable wet tool grinder for all kinds of shop tools.
The water is under instant control of the operator.
When thru grinding, the wheel is left free from contact with the water, and remains ready for the next operation.
Complete description in Catalogue N., and the price is attractive.

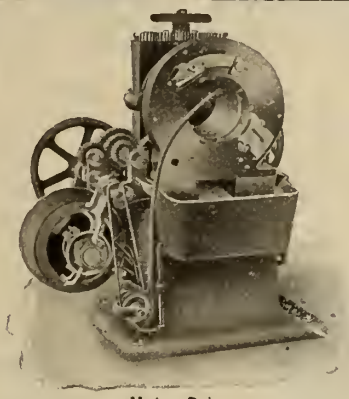
Merrell Motor and Engine Driven Machines



Motor Drive

The motor is connected up with a double switch, so that the machine can be run either right or left. In addition to the motor, power may be applied by either crank or ratchet to the shaft of the pinion which engages the gear wheel enclosing the dies. These machines have a greater range of work and make quicker changes from size to size of pipe than any other combined machine on the market. The machines are made in four sizes—Nos. 5½, 6½, 9½, 11½.

Patent Steam Setter

Will increase cut from five to ten per cent.

Very Simple
Easily Attached
Very Reliable

The following is what one of our customers has to say about this Steam Setter :

" The Steam Setter which you sold us for this season's cut has satisfied us beyond our highest expectations. After using it for more than six months we are convinced that it has considerably increased our cut of lumber and has more than twice earned what it cost."

Write us for full particulars and price.

This is a cut of our No. 75 Tenoning Machine. We regret we cannot explain to you its many points of advantage over other makes of machines in the same class.

The table is of the roller type, moving across the ways with the least possible resistance.

Provision has been made in this machine (as well as all other machines we build) for adjustments of all parts, so that a perfect alignment is assured at all times.

We build a line of machines for Planing Mills, Sash and Door Factories, Furniture, Piano and Organ Factories, etc.

We sell our goods on their merits and we do not build anything cheap, quality being our first consideration.

We presume you are the buyer of machinery such as we supply. We should be pleased to have you correspond with us regarding your requirements. Our entire staff are at your disposal. We solicit an opportunity of explaining to you our goods. It will cost you nothing and you are under no obligation to buy. Ask our representative to call. A line from you will be sufficient.

WE USE CUT GEARS ON ALL OUR MACHINES

Canada's New Lubricating Graphite

Mined and Manufactured in Canada

This new lubricant is prepared from carefully selected ores taken from Canadian mines. In its manufacture the ores are thoroughly pulverized and all impurities removed. The powder is put through a special "air-floating" process to make it impalpable and absolutely free from grit.

Graphite your own Oils and Greases

Use Canada's New Lubricating Graphite, which you know is pure and has been properly prepared.

ITS USES ARE LEGION

As a paint it has staying power, is economical, easily mixed, is a rust preventing preservative for wood and metal; offers the maximum resistance against the action of Ammonia, Alkali, Acids, Smoke, Water, Brine, Sulphur, Fumes, Gases, Chemicals, Extreme Temperatures or Climatic Changes.

Watch for our Ads. and we will interest you. Write for our Catalogues and Booklets and they will convince you that we can save you money.

R. O. HOPKINSON MACHINE WORKS

Special Wire Working Machinery

Waterville, Que., January 19th, 1905

To THE CANADIAN FAIRBANKS CO., LIMITED
Montreal, Que.

Gentlemen:

The 3-H.P. Gasoline Engine I purchased from you last September gives me entire satisfaction. It has been running every day from 7.00 a.m. to 6.00 p.m., and runs all my machines.

I can recommend it to any person wanting a good power.

Yours truly,

(Signed) R. O. HOPKINSON.

If you own a machine shop or use power for any purpose write us to-day for Catalog 100A of Gas and Gasoline Engines.

Modern Canadian Manufacturing Plants.

ARTICLE XII.—Large Wood-Working Establishment of James Davidson, Ottawa.

A Story of Progress.

IN 1874 a modest wood-working shop was started at Mount Sherwood, then a suburb of Ottawa. The men interested were Mr. R. Thackray and his stepson, Jas. Davidson, and his brother, R. J. Davidson. These comprised the firm and included the entire staff of workmen. The output consisted of doors only, and of these about five a day were turned out, all work being done by hand.

Fig. 1—Davidson & Thackeray Plant—Main Corridor Looking South.

The first machine installed was a hand-power rip saw. It was a home-made affair with a balance wheel of wood weighted by sash weights. The motive power was supplied by Mr. Davidson and his brother, while Mr. Thackray was the machine operator. Soon, however, this method was found too slow for the burning ambition of these men, and a 10-horse-power engine was brought into requisition. With them it was the growing time. As the output increased more machinery was added and the prime mover increased in size until one of 75-horse-power was reached. All this time more and more men were being added to the company's list of employes.

Removing to Ottawa.

Mount Sherwood being somewhat out of the way it was decided to move the plant to Sparks street, city of Ottawa. Here an unfortunate train of circumstances followed the efforts of this firm. Within fifteen years three plants were entirely destroyed by fire, resulting in complete loss each time. These fires represented a total loss of $250,000, over and above all insurance, yet the firm bore up each time underneath their loss and paid one hundred cents on the dollar.

To-day everything about the firm and the business is done on a large scale. The factory that at present stands as a monument of enterprise and genius of Mr. Jas. Davidson would be a credit to any city. From the manufacture of five doors a day, and that the only line made, the present capacity is a door a minute, and this only one of many lines. It might be mentioned in passing that besides his active business life, Mr. Davidson finds time to take part in the municipal affairs at Ottawa. He is an ex-mayor and at the election held recently he was returned to the office of alderman with the largest vote ever polled in that city.

The firm owns 150 square miles of timber limit on the Coulonge River. Their mill is operated at the junction of the Coulonge and Ottawa Rivers, an ideal situation. The Pontiac & Pacific Junction Railway runs alongside the limit, where the station of Davidson is situated. Here a village has sprung up, three miles from the village of Coulonge and 80 miles from Ottawa. The mill and woods operations are under the supervision of R. J. Davidson.

The Present Plant.

When early in June, 1904, one of the most disastrous fires that ever occurred in a wood-working establishment laid the magnificent Sparks street factory of Davidson & Thackray in ruins, it was agreed by the old firm that not only

Fig. 2—Davidson & Thackeray Plant—Main Building, Part of Door Department.

were more extensive quarters and enlarged facilities necessary to the successful handling of its extensive home and foreign trade in sash, doors, blinds, mouldings, and other stock items, but that a thoroughly modern mill was needed to facilitate the execution of orders for interior finish, odd wood-work of all kinds, and especially the manufacture of their noted North Star refrigerators and toboggans, which lately have developed into a large department in themselves. The plant which this firm proposed to erect, it was decided, must be thoroughly modern and complete and up-to-date, and much time and thought were given to plans for its construction both by the firm themselves and also by the competent foremen in charge of the different departments. Quietly and unostentatiously those plans have been advanced from stage to stage until to-day the factory of James Davidson in its movement and operation is acknowledged to be not only the most up-to-date sash and door plant in Canada, but it is generally admitted that it is one of the best on the American continent. Four acres of ground are occupied by the factory and warehouse buildings, including lumber and stock sheds, and the location is the best that could have been found in Ottawa, fronting as it does on the Richmond road, which is the main artery leading into the city from the county of Carleton. It also faces the tracks and terminals of the Canadian Pacific and Grand Trunk Railways, giving ample opportunities for unloading cars. The mill, dry-houses and engine and boiler-houses are constructed of brick and are as nearly fireproof as it is possible to make them. The mill proper is 300x200 with an "L" 75x200 feet. The dry-houses are 75x100. They are run by the Sturtevant fan system, the fans being run by a Westinghouse motor of 20-horse-power, and the electric current is supplied by the Ottawa Electric Co. The power-house is brick, 40x60 feet. One timber shed is 22x400 and the moulding shed is a double shed, 80x200.

Fig. 3 –Davidson & Thackeray Plant - Planing Mill Looking East, Stickers in Foreground.

The stable is 24x70 and has accommodation for twenty horses. The firm have private sidings on the Canadian Pacific and Grand Trunk Railways. From these sidings wagons are loaded with material incidental to the sash and door business and loaded directly into the dry kiln, where it is allowed to season and thoroughly dry. This dry kiln, which like the mill and office receives its heat from steam supplied by the boilers, is one of the largest in Canada, having a capacity of 100,000 feet. From this kiln, the doors of which lead immediately into the factory, the lumber passes to the planers and leaves them surfaced smoothly. From these machines it progresses rapidly to others, all so set and arranged that the material is handled without loss of time and without waste of motion. Passing from the planers it is transferred to some of the several rip or re-saws, or automatic tables where cut-off saws divide it into desired lengths, and it goes to other of the numerous machines which fill the main floor of the building. Much of the finished product is manufactured almost entirely by these machines, tended by skilled machine hands. Other work may, however, be so elaborate and delicate in its nature that it must be executed largely by hand, and for this work a large number of skilled bench men are required.

Blower System.

An important feature of the mill equipment is the blower system, which has been installed at a cost of about $5,000. This system, consisting of numerous pipes so located that the dust, chips, shavings, and in fact all waste from lumber in course of manufacture is drawn into them directly from each machine, and by suction drawn into two great main pipes leading to a reservoir known as the Cyclone, from which the waste is automatically fed into the furnaces, thus serving the double purpose of cleaning the mill from refuse and adding to the reduction of fuel account. As noted above, steam heat is supplied throughout all buildings and offices and the employes of the company are assured of comfortable working quarters. The heating and blower system are the manufacture of B. F. Sturtevant Co., Boston, and have been found by the firm to give splendid satisfaction. The apparatus consists of a standard Sturtevant 150-inch fan of the three-quarter housing type, driven by horizontal cen-

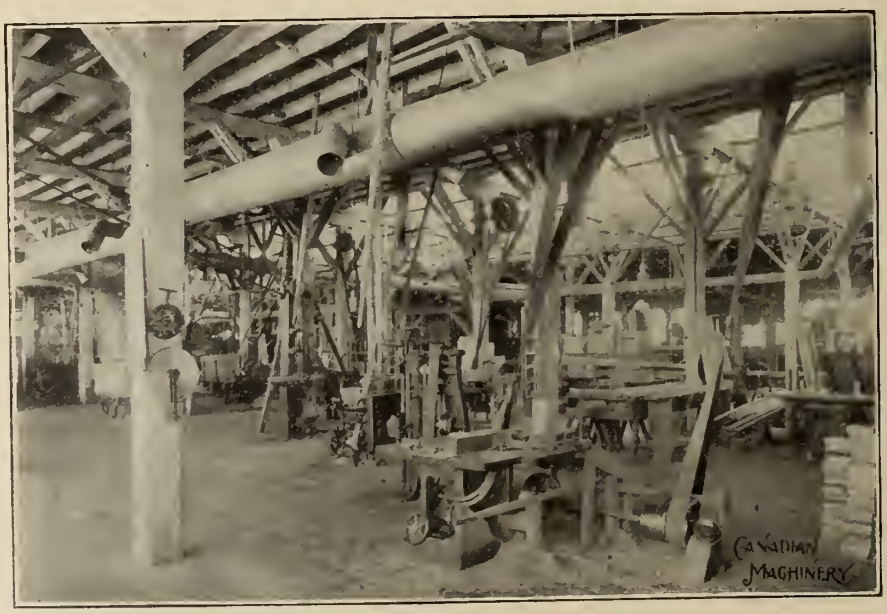

Fig. 4 –Davidson & Thackeray Plant—View in Main Building Looking South-West.

tre crank engine having 7-inch cylinder and arranged to draw the air through a heater containing 12 standard Sturtevant 4-row sections. The air is distributed first through an underground tunnel and thence discharged into an overhead system of galvanized iron piping, carried in each wing of the building. The most important feature of this system lies in the fact that all of the heating surface is massed in a single casing placed entirely outside the building, and a forced circulation of warm air is secured through an extended system of overhead piping with its downward discharging pipes. The building being but one storey, and having so much glass, is naturally hard to heat, but the Sturtevant system has been found to be in this case all that could be desired. In the "L" on the main floor are located the heating and glue rooms, these being equipped with more than the ordinary amount of steam-heated pipes, warmth being a requisite for successful glue work, of which much is done in the production of fine veneered material. Great care is used in this as in every other department of the mill and the output is such as to sustain the high reputation established by the firm. All the machinery has been installed under the supervision of the mill superintendent, Mr. Leander Henderson, one of the most competent men in this line of business in the Dominion. The machinery is the best and latest type, and so conveniently is it arranged that sash and door manufacturers from other Canadian and American cities who have visited the plant have unanimously pronounced it one of the most systematic and up-to-date wood-working plants on the American continent. Electricity is used to light the various buildings, lumber sheds, etc. It requires upwards of four hundred lights, same being supplied by the new Ottawa city municipal plant, lately acquired from the Consumers' Co.

The Power.

The power-house, from which comes the force putting life into the 1,200 feet of line shafting, is a very important part of the plant as a whole, and one which demands a certain amount of attention. The engine installed is one of the Wheelock type, manufactured by Messrs. Goldie, McCulloch Co., of Galt, and is capable of working up to 350-horse-power. Five large boilers, 6x16, are a further portion of the equipment and the power plant is so arranged that if necessary in forty-eight hours by a duplication of engine power, 600 to 700 horse-power can be assured. The boilers mentioned were manufactured by W. J. Campbell, Ottawa, with the patent Dutch oven for burning light fuel, such as shavings, sawdust, etc. The entire fuel used is refuse from the mill. One man only is required for firing the oven, whereas with the same equipment using coal three men would be needed. Part of the power-house consists of a shaving vault 60 feet high and 40x30 feet. On top of the power-house is a separator 8 feet in diameter by 16 feet high, and another on the main mill 12 feet in diameter. These separate the sawdust from the shavings. The sawdust goes into bins directly over the boiler.

Fig. 5—Davidson & Thackeray Plant—View in Planing Mill, Showing Matchers.

Process of Manufacture.

As doors were the only articles manufactured by this firm in its early history it would probably be of considerable interest to follow the lumber that goes into the make-up of a door. From the drays it is loaded on to large trucks in the kiln. After remaining in the kiln for a sufficient time it passes through a dry shed to the main building and down one aisle to the door department without having been handled again. The lumber, which has already been culled, is planed by a large double-surfacer made by the Berlin Machine Works, Beloit, Wis., of special make for dressing up door stock. From the door planer the lumber passes through rip saws, after which it goes to self-operating cut-off saws made by E. B. Hayes, Oshkosh, Wis. All the material is handled from trucks to machine to trucks, thus insuring a minimum of handling. The equipment for manufacturing doors consists of two complete sets, one for dowel door machinery and the other for all other classes. These machines are all so placed that the material passes from one to the other in natural sequence, thus when the lumber

is finished it is handy to the clamping machine.

From the cutting-off saws some parts go to a double-end tennoner made by the E. B. Hayes Company. The stiles go

Fig. 7.—Davidson & Thackeray Plant—Boiler House Showing Feeders from Sawdust Reservoir.

to the stile borer, where they are bored, and the rails to the rail borer. The latter then go to the automatic glueing and dowel driver, where the dowel pins are inserted automatically and glued. This operation leaves them ready for the door power clamp made by H. C. Doman & Co., Oshkosh, Wis. After clamping the doors are all handled through a 72-inch three-drum door sander, made by the Berlin Machine Works, Beloit, Wis. As the process thus described refers to dowel doors, this is the last operation.

The better class of doors go through as odds, a single-end tennoner, door stickers, chisel mortiser, chain saw mortiser, relisher and door clamp.

These, with the exception of some lighter saws, include the equipment of the door department.

Sash Department.

Material for the sashes is cut out next the door department and goes through the same process of planing, ripping and cutting as the former material. Included in the equipment of this are single end tennoner, chain saw mortiser, sticker, relisher and boring machine, where the different operations are performed by skilled workmen.

Window and Door Frame Department.

Machinery here includes cut-off saws, rip saws, window pocket machine, grooovers, beaders, and a large double-headed machine for checking the head and sill of door frame at one operation. Besides these are a drum and disc sander, combination iron saw tables for mitreing, bevelling, etc., and two buzz planers or jointers and a 30-inch double surfacer.

With this machinery is included a large number of carpenters' benches for the manufacture of office fittings, counters and shop fittings, both in hard and soft wood. The woods used here are white pine, white wood, ash, and white and red quarter-cut oak.

Planing Mill.

This is one of the most important departments in the plant. The equipment consists of two large matchers and planers made by McGregor-Gourlay Co., Galt, Ont., and one special hard wood flooring machine made by Hoyt & Brother, Aurora, Ill. Connected with this machine is a self-operating cross-cut saw and an end-matcher made by Goldie & McCulloch, Galt, Ont. The principal material going through the first mentioned machine is pine and spruce. The pine is run into flooring and sheathing, V-jointed and beaded, as well as clapboarding. The spruce is for flooring. Birch and maple and oak are also made into flooring here. At the present time seventy lineal feet a minute of hard wood flooring is run through.

In this department are also a large re-saw made by the W. B. Mershon Co., Saginaw, Mich., and an S. A. Wood double surfacer, as well as one made by McGregor-Gourlay Galt, Ont. One of the latter firm's make of gang ripping saws was also noticed, as well as another manufactured by Hoyt & Brother, Aurora, Ill. Four stickers are included in the machinery of this department and one dowel pin machine for the doors. Two of these machines were manufactured by the Berlin Machine Works and two by McGregor-Gourlay, while the dowel pin machine is the product of the E. B. Hayes works. In addition to these, there are two power feed rip saws for ripping the moulding stock for the stickers mentioned above.

All the moulding stock comes from the kiln uncut to these two power feed saws. This does away with any additional handling whatever, as the operators take the lumber from the cars as they are wheeled out of the kiln, the same as in the door department, thus saving a large amount of work every day that would otherwise be necessitated if such a system were not adopted. All lumber for this department is sorted under cover or in the mill proper. All lumber coming up for the kilns is loaded directly off the sleighs or wagons on to the cars in the dry kiln, and after drying these cars are taken on tracks into the mill and to the particular department for which the lumber is intended.

Box Factory.

A new building 100x100 feet has just been erected to take care of this part of the business, but at present manufacture is carried on in the wing of the main building, as shown in the illustration. Machinery in this department is all of a special nature, the most noticeable of which is a box nailer. It is a combined cleater and nailer, manufactured by the Doig Machine Manufacturing Co., and will drive sixteen 3-inch nails at one operation. Another important machine in this department is the double color box-board printer, manufactured by the Morgan Machine Co., Rochester, N.Y. It prints two colors at one operation and can print at the rate of 150 impressions per minute. Other machinery here includes cross-cut saws, rip saws, box-sizing machines, mitre saws, cleat cutter and champfering machine, as well as several tying machines manufactured by this firm and upon which they control patents.

Fig. 8 Davidson & Thackeray Plant—A Lumber Shed.

Grinding and Sharpening.

This is always an important department in any large wood-working establishment. The grinding and sharpening equipment here is well in keeping with

the modern ideas followed throughout the entire plant.

Besides all necessary small emery wheels and appliances for fitting up moulding cutters, cutters for matchers, shimmer cutters, etc., there is a very complete complement of other machinery. These include band, re-saw grinders, automatic circular and rip grinders, a large machine for grinding planer knives and an automatic grinding and setting machine for small band saws used on scroll work. Two men are kept constantly on this work.

Lumber Yard.

Another noteworthy feature of this plant is the fact that all lumber kept in stock is under cover, which generally comprises over a million feet. These sheds occupy the two sides of the rectangle 300x400 feet. They are 18 to 20 feet deep and 20 feet high. In the centre is another 100x250 feet, with a plank driveway through the centre, 22 feet wide, shown in the photograph. One side of this shed has been finished for stock sash and stock doors. The other side is double-decked principally for dressed stock, such as mouldings. This shed is one of the best of its class in Canada and probably has no superior on this continent.

The Staff.

The staff that work so harmoniously under Mr. Davidson is composed of the following gentlemen: Leander Henderson, manager and mechanical superintendent; Mr. Ouellette, in charge of refrigerator department; E. P. McGrath, foreman of the factory; Messrs. Frank White and Robert Massie, in charge of the estimating departments; Mr. Joseph Dawson, sales agent; and Mr. A. G. Rose, accountant.

The foregoing description can give the reader but a faint idea at best of the splendidly equipped and well organized plant of Jas. Davidson, of Ottawa, and it is not only a credit to Mr. Davidson, but an evidence of progress to the city of Ottawa as well as to the country at large.

THE NICHOLSON FILE CORPORATION.

HEREWITH will be found illustrated three extensive factories belonging to the Nicholson File Company. This company is operating seven large plants, including their Dominion works located at Port Hope, Ontario, giving employment altogether to over two thousand hands, manufacturing files and rasps exclusively. Their combined daily production exceeds 120,000 files and rasps of every size, shape and cut, and it is claimed that not only are they the largest manufacturers in the world but that their output is greater than that produced in the factories in England, France and Germany combined.

The Nicholson File Company was incorporated in 1864 by the late Wm. T. Nicholson, father of S. M. Nicholson, now president of the company, he having invented what is known as the increment cut file which rapidly superseded all other machine cut files, and is to-day preferred by expert mechanics to the best hand-cut files on account of their uniformity of cut and wearing qualities, consequently there is a growing demand for these files in all the large manufacturing centres of Europe, and the larger industries such as railroads, electrical engineering companies, and machinery manufacturers use the Nicholson increment cut files.

Although the Nicholson File Co. have purchased within the past six years nearly all the prominent file plants on this continent, they have not taken advantage of the situation and entered into any combine, neither have they advanced prices. On the contrary, the several plants which they now operate manufacture certain brands and kinds for which they are best adapted, with the result that they are now enabled to produce a very superior article at a much lower price than heretofore, and they are giving the consumer the benefit by supplying the different brands at very reasonable prices both on this continent and in foreign countries, and the result of forty-odd years' experience enables them to give an absolute warranty with all the goods manufactured by them. They have expended a large amount of money in connection with their Dominion works plant during the past three years and are now in a position to execute the largest orders promptly.

WORK AND WORRY.

"It is not work that kills men; it is worry. Work is healthy; you can hardly put more upon a man than he can bear. Worry is rust upon the blade. It is not the revolution that destroys the machinery, but the friction."—Henry Ward Beecher.

CANADIAN MACHINERY
and Manufacturing News

A monthly newspaper devoted to machinery and manufacturing interests, mechanical and electrical trades, technical progress, construction and improvement, and to all users of power developed from steam, gas, electricity, compressed air and water in Canada.

THE WOODWORKING MACHINERY OUTLOOK.

EMPHASIS is given to the view that the outlook for woodworking machinery in Canada assumes a brightness unknown before by the fact that one of the largest manufacturers of this class of machinery is about to build a new plant double the capacity of the one now operated. At present there is a demand for high-grade woodworking machines that must continue as the country becomes settled northward into the timber districts.

An example of an as fairly equipped woodworking plant as may be found on the continent is described in the first article of this issue, showing the growth from a small beginning to a plant of which any city might be proud. The same possibility lies ahead of others who go about it in the right manner. The demand for the output of these factories is increasing, the raw material is to be had in unlimited quantities, and every month sees many such new industries commencing operations.

A visit by a representative of Canadian Machinery during the past month to the different manufacturers of woodworking machinery in Western Ontario reveals the fact that without exception they are enthusiastic over last year's business and glowing with the expectation of an increase even over the record business of the past twelve months for the year to come. The opening up of new districts both north and west suggests planing and saw mills at every centre. The immediate prospect is in British Columbia, where a hitherto unthought-of development is taking place, to which province consignments are going as rapidly as the machines can be turned out.

In regard to the design of new machines, it might be said that the tendency is decidedly in the direction of a heavier pattern. This began about six years ago with band saws, but not until within the past two years has the same been true of other standard woodworking machines. Cutting speeds have been increased, with the result that greater rigidity is imperative.

PRODUCING STEEL THERMO-ELECTRICALLY.

SAMPLES of steel produced directly from the ore, the first to be made in Canada, have been received by Mr. T. W. Gibson, director of the Ontario Bureau of Mines, from J. W. Evans, a mining engineer of Deseronto. One was made from the sulphurous ores of the Coe Hill Mine in Hastings county, and the others from titanium ore of the Horton Mine.

It is well known that an excess of sulphur reduces the value of iron ore to the point of making it next to worthless, depending on the percentage, and titanium renders iron ore extremely difficult to reduce. In view of this, the production of steel from such ores is all the more interesting and important.

However, it must not be lost sight of that this is merely a laboratory experiment, and demonstrates nothing regarding its commercial practicability. Some mild sensation has been raised over this, and possibly not without reason if from a scientific viewpoint alone, but until data and figures are available regarding the cost of producing steel in this manner it is useless to conjecture as to its effect on the steel industry of Canada.

GRANTED SPECIAL PRIVILEGES.

AT the meeting of the Engineers' Club, of Toronto, on January 11, a motion was passed extending to the editors of Canadian Machinery, and of other Canadian technical papers, "the privileges of the club rooms for the ensuing year."

Does the average reader appreciate the significance of this little act of courtesy? It is of enough importance to note in passing, for it serves to illustrate a point that some readers, and particularly some advertisers, frequently fail to grasp.

Why should the courtesy of the privileges of the club rooms of one of the most influential engineering bodies in Canada be extended to the technical press, and yet be withheld from the daily press? The answer is concise—because the members of the club have learned that the daily press is not in a position to deal intelligently with technical matters, and, further, that the technical press, in addition to treating the various subjects discussed intimately and intelligently, can be relied upon to cover the entire technical field. Moreover, they have learned that the technical man, the machinist, the superintendent, the engineer, the manufacturer, look for the technical news in the technical papers, not in the daily press, and so take this safe, as well as thorough, method of having the reports of their meetings placed before those interested.

To carry the query another step, what is back of this? The thought that the proper medium through which to reach the technical man is the technical paper. Moreover, the more progressive and up-to-date the treatment of technical matters the more influential and consequently the more effective the paper as an advertising medium.

QUALITY RATHER THAN QUANTITY.

CHARLES M. SCHWAB has uttered a note of warning to manufacturers in America regarding their output. A recent visit of his to the industrial establishments of Germany showed him clearly the reason of the German's success in the metal and other industries. Their love of research has taught them a thoroughness unheard of in this country. They aim at perfection, and are not satisfied until their object is achieved. Quantity with them is not thought of until quality is assured. They read and think and study and experiment, until some definite result has been attained. Himself a manufacturer on a large scale, Mr. Schwab was not slow to realize what the adoption of similar methods would mean in this country, and has already acted on his own suggestion regarding a better quality of output. He advocates more attention being paid to higher grades of manufacture.

Herein is a lesson for every manufacturer in Canada. With an ever increasing demand, our manufacturers are finding difficulty at times in keeping up with orders. Speed, economy of production, and quantity, are paramount, the inevitable result of which is a tendency to forget that quality should be the first consideration. We in this country cannot afford to overlook the object lessons of older established countries. Our prospects today are not excelled, and our resources are incomparable, but we must remember that even so we cannot lead in industrial pursuits unless we lay broad and deep the foundation of quality, and having secured this the superstructure of quantity will rise in towering strength.

EDITORIAL NOTES.

Unless the Ontario Government acts with promptness and decision regarding the validity of the Cobalt mining claims there is bound to be a regular furor of legal battles and much bitterness before matters are straightened out.

* * *

It is estimated that the value of the mineral output of British Columbia during last year was over twenty million dollars. The gold values were the greatest, being $5,750,000, followed closely by copper, at $5,400,000. Other minerals in order of value were coal, lead, coke, building materials and zinc.

* * *

Future generations will appreciate more, perhaps, than the present efforts of those who called together the Canadian Forestry Convention at Ottawa on January 10, 11 and 12. It is none too soon in our national history to commence a work that will provide an asset of no small amount in the years to come.

* * *

Interest is being aroused amongst lumbermen in Cambria county, Pa., towards the timber wealth of Ontario. Two gentlemen have been in Toronto recently from that district with a view to finding out the opportunities for investment. They represent interests prepared to spend from $500,000 to $1,000,000 in lumber operations in Canada.

* * *

In spite of the unfavorable outlook during the first three months of the past year, the railway companies found it the best in their history. Snow blockades and consequent cessation of traffic augured ill at the commencement, but enough subsequent business was done in excess of other years to make nineteen hundred and five the banner year in railway circles.

* * *

Attention is called to a series of articles, commencing with this issue, on the "Improvement of the Steam Boiler," by Mr. Peter Bain, designing engineer of the John McDougall Caledonian Iron Works, Montreal. The subject is one upon which the author, from his wide experience, is well calculated to write, and is essentially of interest to all users of steam power.

* * *

According to one of the daily consular and trade reports, issued at Washington, Turkey is ready to import agricultural implements of all kinds, and many lines of machinery, including flour mill, mining, laundry, small ice making, grain cleaning, wood working for doors, sash and blinds, cotton gin, box making, etc. The great demand is for simple machines of small dimensions.

* * *

Beautifying towns and cities in Canada is a live topic at present. The employes of Goldie & McCulloch Co., Galt., have gone at the matter in the proper manner by forming a society with that in view, wherein each member undertakes the individual responsibility of improving and making attractive his own premises. Other towns might follow this initiative to their material advantage.

HENDERSON ROLLER BEARING MIX-UP

Auditor's charges, says President Simpson, may mean Penitentiary for R. I. Henderson.

A sensation has been created in manufacturing and investment circles during the past month in connection with the affairs of the Henderson Roller Bearing Co., of Toronto, resulting in an airing of the business in court, where some lively and dramatic scenes ensued and where startling evidence was given.

As a result of writs issued against the company, a winding-up order was granted by Chief Justice Falconbridge on Saturday, Jan. 13, but on the following Monday, on the application of another petitioner, a stay in proceedings was allowed. This gave a chance to have the principals in the case make their statements in court, these being D. Burke Simpson, president, and G. F. Marter, vice-president, who maintained that the company as it existed was hopelessly insolvent, and A. E. Henderson, secretary, who denied that this was so.

Pending this decision, permission was given the shareholders to hold a meeting which was called for Friday, Jan. 26, when a reorganization was recommended in preference to liquidation. As far as all evidence goes, the affairs of this company are certainly in a bad way.

To go into history, about five years ago A. E. Henderson, then a Methodist minister of Woodbridge, secured the patent for the invention that now bears his name. Business men of Woodbridge, together with some Toronto capital, formed a company, to exploit this bearing, called the Toronto Roller Bearing Co., with a capital of $40,000 in shares of $100 each. After some experimenting and procuring patents in almost every civilized country in the world, the idea was conceived of making this the parent company to sell the rights to other companies to manufacture the patent, which at this time had not been given a really satisfactory commercial test.

The next step in the affairs of this organization was when the Henderson Roller Bearing Mfg. Co. was formed, capitalized at $1,000,000, to take over the patent rights for Canada only and manufacture the bearings in this country. They were to pay the parent company for this privilege $500,000—$100,000 in cash and $400,000 in stock in the new company. The stock of this new company was boomed and advertised in such a manner that single shares rose in value to over $125, during which time some goods were manufactured, but which, according to the statement of some of those interested, were being placed on the market at a fraction of their cost to manufacture. It was apparent to some of the shareholders that matters had not been going satisfactorily, as, according to the statement of Mr. Marter, the board of directors had lost confidence in Messrs. Henderson and the managers were asked to resign. The officers all sent in their resignations with the exception of A. E. Henderson, then secretary and treasurer, who asked that he be left with the secretaryship. A new management was appointed, with D. Burke Simpson as president, G. F. Marter, vice-president. The balance sheet issued on Nov. 30, 1905, is of interest. It shows $478,000 of stock paid in, with assets of $117,000, and liabilities of $45,000, leaving nominally $72,000 of assets besides the alleged value of the patent to answer the $478,000 of stock paid in. The statement shows the value of this to be $500,000 as a cash asset, giving the company, by the statement, a contingent reserve of over $93,000. The question many of the shareholders asked was, what became of this large amount of money, since no showing of this appeared in the statement.

Matters became more and more unsatisfactory to many of the shareholders, resulting in a number of writs being issued against the Henderson Roller Bearing Co. on the ground of alleged misrepresentation, as a large number of the shareholders bought their stock with the proviso, "We hereby agree that if you are not satisfied with your holdings of this stock, after twelve months, we will give you back your money with 25 per cent. advance and 10 per cent. for the money during the time we have held it." Signed with the rubber stamp of the Henderson Roller Bearing Co. per R. J. Henderson, manager.

In view of the number of these writs, the winding-up order was issued by Chief Justice Falconbridge on the recommendation of the financial statement issued by Messrs. Simpson and Marter. In the proceedings to set aside this winding-up order, the company's affairs were placed in the limelight of public attention for some days, the conspicuous features of which were the bitter denunciation by Messrs. Simpson and Marter of the Henderson mis-management of the company. It was stated by Mr. Marter that the company had been going behind between $4,000 and $5,000 a month and that for over $400,000 invested there was only $30,000 worth of business done. An affidavit filed at Osgoode Hall by Auditor Edwards, of the company, estimates the loss in the manufacturing end up to Nov. 1 of last year to amount to $80,000. It was claimed by A. E. Henderson that Messrs. Simpson and Marter had acted in bad faith in placing the affairs of the company before the creditors. The question was adjourned until the meeting of the shareholders should have taken place, which was done on Friday, Jan. 26.

At this meeting serious charges were made by the officials of the company, the discussion lasting from 9 o'clock in the morning until nearly 7 o'clock in the evening. G. F. Marter opened the business proper with a speech of a condemnatory character in which he declared the company to be hopelessly insolvent. He was followed by a speech in similar vein by Mr. Simpson, in which he stated that the company was not only insolvent, but that the invention was useless. A. E. Henderson, inventor of the bearing, spoke for more than two hours, when he attempted to vindicate the character of the invention.

An evidence of the seriousness of this discussion is seen in the fact that in speaking of their desire for an audit, Mr. Simpson said that the auditor had made charges that meant only one place, and that the penitentiary, for the manager, R. I. Henderson. "We paid $21,000 and there were $31,000 of debts at the time Mr. Henderson said there were only $1'4,000." They had not been able to get the particulars regarding the new building being built by the new company, and when built he did not know what the factory was to do, as a traveler had come in, after being all over the country, with a single order of $40.

In his defence, A. E. Henderson said that it was unfair to have his brother appear as receiving large sums of money unjustly. Money had to be expended for the promotion of any enterprise. He showed a list of orders that had been received before the present crisis had arrived. The financial statement given at the meeting of the audit of Edwards, Morgan & Co., made on the suggestion of Chief Justice Falconbridge, as submitted by Mr. Marter, is in part as follows:

RECEIPTS.

Allotted on patents.....	$200,000.00
Calls paid	261,255.00
Premiums paid	23,270.00
Share notes	18,450.00
Credit for machinery	19,094.82
Borrowed	25,678.20
Sales, $47,915.19, less amount outstanding....	35,363.16
	$583,111.18

Of this amount $346,678.31 is represented by: Patents, $240,272, and the balance in machinery, tools, drawings, fixtures and buildings, the latter amounting to $23,654.53. For $236,423.46, no assets remain.

Against this must be set income of $61,585.19, leaving a new impairment of capital $175,703.27.

Pending a final decision, the court adjourned the case from Monday, 28th inst., for three weeks, in order that all possible chance be given the shareholders for a reorganization.

Some confusion has arisen in the minds of many regarding the manufacturers of anti-friction bearings, with the result that the names of other firms have been associated with this one. It might be said that there are two other firms manufacturing anti-friction bearings, namely the Chapman Double Ball Bearing Co., of Toronto, and the Canada Bearings, of Hamilton, neither of which has any connection whatever with the Henderson Roller Bearing Co.

ENGINEERING NEWS

AND BUSINESS NOTES

SOCIETY OFFICERS.

Canadian Society of Civil Engineers.

Officers for 1905: President, Ernest Marceau, Montreal; treasurer, H. Irwin; secretary, C. H. McLeod. Rooms: 877 Dorchester St., Montreal.

Canadian Mining Institute.

President, George R. Smith, Thetford Mines, Quebec; secretary, H. Mortimer Lamb, Victoria, B.C.; treasurer, J. Stevenson Brown, Montreal.

Toronto Branch A. I. E. E.

Chairman, H. A. Moore; vice-chairman, R. G. Black; secretary, R. T. McKeen.

Marine Engineers.

Grand president, E. J. Henning, Toronto; grand secretary, Neil J. Morrison, St. John, N.B.

Engineers' Society, Faculty Applied Science, Toronto University.

President, T. R. Loudon; recording secretary, F. A. McGivern; treasurer, B. W. Marrs; corresponding secretary, C. S. Shirriss.

Canadian Electrical Association.

President, A. A. Wright, M.P., Renfrew, Ont; vice-presidents, R. G. Black, Toronto, John Murphy, Ottawa; secretary-treasurer, C. H. Mortimer, Confederation Life Building, Toronto.

Canadian Association of Stationary Engineers.

President, Wm. A. Sweet, Hamilton; vice-president; Jos. Ironsides; secretary, Wm. Outhwaite, Toronto, conductor, Ed. Grandbois, Chatham; doorkeeper, Chas. Kelly, Chatham.

Ontario Association of Stationary Engineers.

President, Geo. Fowler, Toronto; vice-president, W. F. Chapman, Brockville; treasurer, Charles Moseley, Toronto; registrar, W. G. Blackgrove, Toronto

Canadian Railway Club.

President, S. King; secretary, James Powell, chief draughtsman motive power department, G. T. R. treasurer, S. S. Underwood, chief draughtsman car department, G. T. R.

Engineers' Club of Toronto.

President, F. L. Sommerville; treasurer, W. J. Bowers; secretary, Willis Chipman, Rooms 96 King St. W.

Engineers' Club Annual Meeting.

AT the rooms of the Engineers' Club, of Toronto, the seventh annual meeting was held on Thursday evening, January 11, at which there was a large attendance of enthusiastic members, with Mr. R. F. Tait, president, in the chair. The report of the executive committee showed a membership of 145, and further pointed out the fact that the past year had been an unusually prosperous one for the club. The report of the treasurer showed a balance of $713. During the year the opening smoker had been held, and the club's annual dinner, both of which were an unqualified success. The reports of the various committees all went to show the progress made by the club. The committee for revising the constitution was appointed, consisting of Messrs. Bowers, Gemmill, Sommerville, Tait, Canniff, Smith, and Chipman. The election of officers resulted as follows: President, F. L. Sommerville; first vice-president, C. B. Smith; second vice-president, J. G. Sing; directors, J. S. Fielding, A. M. Wickins and C. M. Canniff; treasurer, W. J. Bowers; secretary, Willis Chipman.

The privileges of the club were given to the editors of Canadian Machinery and other technical papers in Canada, for which courtesy the thanks of this paper are herewith extended to the Engineers' Club.

The event of the evening was the reading of the retiring president's valedictory address, in which Mr. Tait gave a rousing resume of engineering progress in Canada during the past year.

Mr. F. L. Sommerville,
President-Elect Toronto Engineers' Club.

He pointed out that Canada had every reason to be proud of the industrial development during 1905. Particularly was this noticeable in steam railroad work, an eloquent portrayal of which was given, showing the commencement of the Grand Trunk Pacific, the completion of the Canadian Northern to Edmonton which was finished very recently, the advances made by the Canadian Pacific, the double tracking of the Grand Trunk Railway from Montreal to Sarnia, and the building of 150 miles of the Temiscaming & Canadian Northern Railway by the Canadian Government, the chairman of the Railway Commission being Mr. Cecil B. Smith, a member of the Toronto Club. The wonderful electrical development at Niagara was given some prominence, in which the speaker pointed out that there was already on the Canadian side 60,000 h.p. available for manufacturers, and that there would soon be 400,000. Next to this was the work done at De-Cew Falls, near Hamilton, where 40,000 h.p. could be developed. Another important step in this line was the power at Port Arthur, where a drop of 120 feet was being utilized. Among other places where additions had been made were Lachine, Chambly, and Shawinigan Falls. Then, again, there had been no uncertain step in the steel rail industry. Canada was now making steel rails of the highest grade, and unable to supply the demand, Bessemer rails being made at Sault Ste. Marie and open hearth rails at Sydney. Along the line of structural work four large firms were located at Walkerville, Hamilton and Montreal, turning out the finest class of engineering and building construction. In locomotive building important strides had been made. Ship building had made some advance, there now being works located at Collingwood, Port Colborne and Toronto. Although little had been done in extending our canals, this was something that was bound to materialize with the further development of the country. It was impossible to go into the engineering details of British Columbia, the northern country and the Maritime Provinces, but it was with enthusiastic pride he was able to chronicle the awakening in his beloved country of an area of progress such as she had never before seen.

A pleasant feature of the evening, following the chairman's address, was the presentation of an alligator traveling bag to Mr. Willis Chipman, the energetic and untiring secretary of the club. Refreshments were then served, after which the meeting was adjourned, all present voting it one of the best that the club had yet had.

* * *

Invitation to England.

An invitation has been received from the Institution of Electrical Engineers of Great Britain by the secretary of the Canadian Electrical Association, extending to the members of the latter society a cordial invitation to visit Great Britain in 1906, as guests of the institution. While this invitation is highly appreciated by the association, it is regretted that it is impossible to organize a special party, although no doubt individual members will avail themselves of the kindness of their British electrical friends.

GOOD COMPANY.

"Associate with men of good judgment, for judgment is found in conversation, and we make another man's judgment ours by frequenting his company."—Fuller.

Natural Selection Applied to Industrial Arts

Or the Law of the Survival of the Fittest

By Egerton R. Case, Solicitor of Patents, Toronto.

(Registered in accordance with the Copyright Act.)

IT occurs to me that it would be of considerable interest to draw a parallel (as far as possible) between Darwin's law of natural selection, or the law of the survival of the fittest, and the best rule for an inventor to follow in inventing, so as to prove the procedure I (and perhaps others) advocate embodies a law that is constantly at work in organic beings.

Preservation of Elements.

Darwin defines natural selection as implying the preservation of individual differences and variations that arise and are beneficial to the being under its conditions of life, and the destruction of those which are injurious.

There are gradations in the state of perfection in the development of an invention, as truly as there are gradations in the state of perfection in the development of organic beings ; and it is only through a thorough knowledge of such "states of perfection" that an inventor can reach the highest success.

As is well known, all the modified descendants from a widely diffused species, belonging to a large genus, will tend to partake of the same advantages which made their parents a success in life ; the same way with inventions belonging to the same class ; therefore, the law of industrial arts development implies the preservation of those elements and process steps that are beneficial to the invention, the discarding of those elements and process steps that are injurious thereto, and the combining with the beneficial elements or process steps new elements or process steps that will make the invention a modern success.

Ideal for Inventors.

According to the spirit of this article, the inventor would naturally take up the art he is most familiar with, and pick out therefrom some invention (and there are many of them) that has failed for want of some improvement to be most valuable. By studying carefully the state of the art relating to this invention, the inventor will have before him the elements that have made each succeeding invention a success over the immediately preceding ones, and will then have the foundation for the development of further steps. In other words he will possess the genealogical succession, so to speak, of the beneficial elements chosen from the prior state of the art, new elements that will make the invention a modern success, and thus follow after an industrial manner the law at work in nature whereby organic beings are developed and equipped so that they can best exist under the then existing conditions of life. By following further this law, it is apparent that new genera and species of inventions will of necessity be developed from time to time, as are new genera and species developed in organic beings.

The charge may be laid against this plan that it would tend to make inventors less original, that is, cause them to copy too closely the existing inventions in the prior art. But careful thought will dispel this belief, as above noted. Even if an inventor determines to work upon the original lines, he must acquaint himself with the prior state of the art, in order that he may successfully keep away from the beaten paths of prior inventors.

It is well known that for every generic invention, there are many secondary inventions. So it is perhaps in connection with secondary inventions that a knowledge of the law set forth in this article will be most useful.

When an inventor goes blindly to work, that is, without any knowledge of the prior state of the art, he spends much time and money in traveling well-beaten paths made by the patient toil of previous inventors ; whereas, if he followed out the plan herein set forth, he would soon acquaint himself with the successful and unsuccessful steps made by his predecessors, and act accordingly ; this is an indisputable fact.

Because an inventor finds that all through an art certain elements therein have been retained, it does not follow that he need combine these elements in the same manner. The requirements of the case will, of course, determine this, coupled with the inventor's mental capacity.

Relation to Darwin's Law.

I do not say that, between my statement of the law to be observed in developing inventions, and Darwin's law above cited, there is a complete parallel. The inventor, of course, has more immediate freedom in his choice of combination of elements than if he were working through a process so slow as that of natural selection. But it would seem that he is bound to recognize and adopt those elements in prior inventions that have contributed to, or that have been the sole cause of, the success of same.

It is well known that inventors oftentimes find great difficulty in making improvements or fully developing their inventions in order to make them commercial. When these periods or states of non-development are taken into account, it appears to me that there is quite a parallel between the development of an invention (particularly a complicated one) and the law of natural selection. When the inventor cannot at once make the step or improvement he wishes, it naturally follows that he cannot draw upon his past experience, and his knowledge of the prior state of the art, in order to supply that defect ; consequently a mental process (which I might term mental natural selection-inventing) must be gone through before the inventor can arrive at the result he is aiming at. The more fertile the brain in which the idea has lodgment, the quicker will the mental powers absorb, so to speak, that idea, and give birth to it in concrete form. So likewise in the development of the organic being ; the more suitable the conditions, the quicker will a genus or species be developed that can best exist under the then existing conditions of that period of life.

The Natural Invention.

As natural selection will never produce in an organic being any structure more injurious than beneficial to that being, it follows that when an inventor proceeds along the right lines of development, he will naturally use elements that will always contribute to the success of the invention. Natural selection tends only to make each organic being as perfect as, or slightly more perfect than, the other inhabitants of the same country with which it comes into competition. Consequently the properly-directed efforts of an inventor must essentially produce as good or better an invention than those prior thereto, and with which it must inevitably come into competition. The chances are greatly in favor of a better invention being produced, as all inventive effort is exercised for that very end.

If I have touched upon a method of development well known of organic beings so as to try and prove to inventors that there is an easier or more natural method of reaching their goals than is now generally practiced, and succeed ever so little, I shall be content. When

we look around us and consider what humanity at large owes to the inventor of all nations, we must acknowledge our great indebtedness to him. His success is many times purchased by the practice of great personal privations, and often without reaping the rewards his heroic and unselfish efforts have merited.

Many inventors will ask how they are to get knowledge of what inventions have been already made in a particular art. The best way to procure this information is to get copies of all the patents granted in that art.

As certain as day follows night, if an inventor proceeds in his investigations after the manner I have endeavored to prove to be the correct one, he will obtain the maximum success with the minimum expenditure of time and money.

What I have herein stated relative to the development of the industrial arts applies with equal force to the development of the fine arts.

Improvement of the Steam Boiler

By Peter Bain.*

NECESSITY for the best in steam boiler material, design, workmanship, management, legislation, supervision and inspection is certainly more urgent in these opening years of the twentieth century than it has been since its introduction and development as a mighty factor in the evolution of the civilized world. Unlike its contemporary, the reciprocating steam engine, the zenith of almost practical perfection has not been reached, nor has its existence been so seriously and successfully challenged. The steam turbine, rapidly superseding the reciprocating steam engine, gives continuity (I am almost disposed to call it permanency) to the steam boiler, making at least equal demands on its strength, safety, weight, compactness, efficiency and capacity, and opening up more extended spheres of usefulness.

This, I take it, calls for the application of increased ingenuity, skill and conscience on the part of those interested. Affecting as it does the convenience and safety of the public, the competitive platform of the boiler manufacturer, the maximum return in efficiency and economy to the steam user, the quality of the steel works output, the education and training of designers, tradesmen and attendants, the most suitable tools and appliances, it is apparent no apology is necessary for discussing through a series of articles in Canadian Machinery this important and far-reaching topic.

Differences of opinion exist all the way through as to the rightness or wrongness of certain conclusions (proved or otherwise) which regulate certain courses of action. Of these I am perfectly aware, yet although suggestions here thrown out may jar on minds as competent and more so, as long experienced and more so, than that of the writer, it is to be remembered that we are not the whole show, that a young generation of engineers and boilermakers is growing up around us, alert, prying, pushing, with heads clear, minds unbiased by familiarity and experience, open to test and prove, and put into practical and progressive effect what is best in their instruction and reading, and what will certainly make for improvement.

Again, it is necessary, even at this late hour of the day, to enlighten, in addition, the general public and allied and associated trades, having already preconceived ideas and opinions in large measure erroneous, such ideas and opinions being nothing more or less than conclusions that because a steam boiler is uncomely to an untrained and inexperienced eye, is devoid of polish and glitter so necessary in the artistic, is minus other (in its case) useless adornments, any conglomeration of plates and rivets (so long as weight is assured), thrown together by a handy man, constitutes all there is to it.

The first article will discuss the important question of

Legislation.

Legislation is absolutely necessary and should in each country be the law for all. Were this consummation reached nationally, the step to international codes of rules would be easily attainable, for the steam boiler is to all intents and purposes the same the world over, and the same ideal perfection is sought. Such legislation, then, from the national standpoint, and not from the provincial and civic, is really the main point, and in so far as it affects our Dominion, let me refer to it. It should be the expressions of a council of representative men, a commission if you like, whose patent of being has the seal of state, whose deliberations and conclusions are untrammelled by such seal, and whose integrity of character and fitness for the work are beyond question. Such men are no "rara avis" in the engineering world, and their recommendations and findings incorporated in the statute book would tend mightily towards an ideal boiler.

Our Canadian Manufacturers' Association, an organization which has the best interests of our country at heart, is to my mind best fitted to put this question on a proper basis. Could not a section of those directly concerned, supplemented by the addition of the expert advisers of each individual manufacturer and consulting engineers of authority and repute be constituted? Codes of rules, the outcome of the deliberations of such a body, backed by the weight of the whole manufacturers' association, could not fail to have the support of the public, and would consequently become law readily. Existing rules there are in abundance, yea, in superabundance, and it is just here that the weak spot is.

The law for the east should be the law for the west, the law for the city that of its suburbs, and the enforcer of the law, representative government advised and guided as stated. Those who guard the law should be men of honor, fearless in the discharge of their duty, and those who manufacture should respect the law to its uttermost limit. Much hard work lies before such a commission. Much wrangling and discussion is ahead. Many imperfections, which time only will eradicate, will be apparent in the rules, and particularly to those persons whose pet ideas have not been incorporated; but out of all a much improved boiler will be evolved, and what is not of little importance, a fairer and more satisfactory competitive manufacturers' platform will be established, a point in its ultimate bearing which affects everybody more or less.

Young, then, though we be as a manufacturing country, it may be our lot to set up the basis from which international codes of rules will govern all steam boilers, and there is no reason why we should not be in the forefront. We have resources unlimited as a country, and as individuals we have a fair share of genius, ability, experience and push. While water power, on account of our natural resources, will necessarily be largely utilized, and electrical power also play an important part, it remains that steam power there must be, and to the extent of the adaptability of our generator will be the extent in our country's development of the part it will play.

* Designing Engineer, John McDougall, Caledonian Iron Works, Montreal.

Designing a Wood-Working Molder

By T. C. Robertson.

ARTICLE II.

ATTENTION was called in January article to the belting of molding machines from rear end and some of the advantages derived therefrom. Going more fully into this we find by reference to the accompanying diagram a

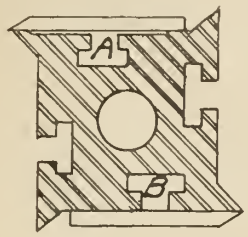

FIG 1

marked advantage upon the wear of cutter head bearings.

First let us note carefully the effect of the pull of knives as they enter the cut and we will see the pull is downward, thus bringing pressure upon bottom part of bearing. The pressure is increased or diminished according to manner of belting, as will be seen by consulting diagram. In belting from front end, the tight side of belt shows a pressure upon bottom side of bearing in addition to that effected by knives and therefore causing greater trouble in wear and heating. In belting from rear end, the pull of belt is in the opposite direction and relieves pressure caused by pull of knives in cutting. There seems to exist in the minds of many operators of wood-cutting tools a misconception regarding the wear caused by the work done. A careful examination of bearings after cutter-head journals have been removed

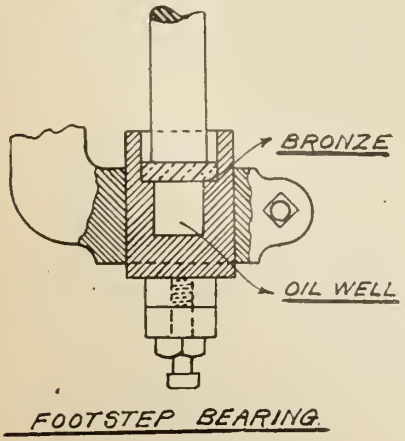

Fig. 2.

will show that the cap has been subjected to very little wear, even in cases where pull of belt has been in direction of cap. The fact is the only time when wear occurs on cap is when there is no cutting done.

Another important advantage gained by belting from rear is an increased amount of power obtained from belts which run side heads. By having the belt delivered in a straight line from side head pulley a perfect contact is obtained, thus giving a larger percentage of power. The power of belt is also increased by the use of pneumatic pulley shown in diagram. It consists of a spiral groove which extends around the face, connecting with exits for the air to pass from between belt and face of pulley. The advantage of this must be apparent when we know the belt hugs the pulley ever the entire bearing surface, with no air cushion to interfere, thus giving according to actual test a gain of about 30 per cent., besides preventing heating of bearings.

Another important feature that should be considered in molder construction is the design of cutter-heads. It will be noticed by referring to Figure 1 that the cutter-head and knife do not come in contact at (A). When bolted down there is a firm and close contact next to cutting edge, thus preventing any possibility of shavings packing in between knife and head. The old method of fastening is shown on same figure at (B), and experience shows that in some kinds of wood, shavings will pack in directly under cutting edge and sometimes strain knife to breaking point.

The footstep bearing for side heads of molders has received much attention from designers, and a number of devices have been adopted to insure a bearing which will endure the wear and avoid heating. The accompanying diagram shows one which has given good satisfaction in every particular. Attention has been already called to the advantage gained by belting from rear of machine, and among these is a minimum of wear upon footstep bearing, as the downward pull is in a large measure eliminated.

The bearing consists of an adjustable step containing a bronze bearing beneath which there is an oil well which supplies oil through a wick inserted into suitable grooves in bronze bearing and terminating in oil well, causing a constant circulation of oil to surfaces of contact. Very little attention is required after supplying oil to reservoirs.

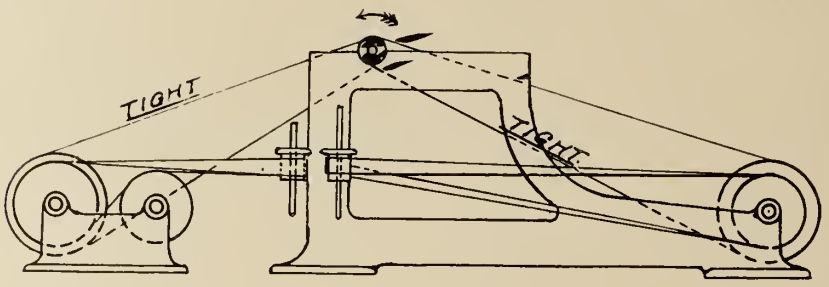

Fig. 3—Belt Arrangement..

DURHAM CEMENT WORKS.

Reference was recently made to the proposed removal of the cement mill belonging to the National Portland Cement Co., at Durham, to some other point, owing to a supposed absence of raw material in that district. The mill has since been closed down and a hot time is promised at the annual meeting which is to take place soon. The company was originally organized about three years ago, the promoters taking one-quarter of the million dollars capital as their remuneration for floating the concern. During the first couple of years about $700,000 was sunk in buildings, plant and experiments, and stock fell to rock bottom figures. Last year, however, the company did business at a considerable profit, and as an investigation has proven that there is a large supply of high class marl near Durham, the local stockholders who have their money invested in the enterprise, are securing proxies and preparing to oust the present directors, and install a new board who will continue the present works and endeavor to produce a dividend for the stockholders.

FRIENDSHIP.

Get not your friends by bare compliments, but by giving them sensible tokens of your love. It is well worth while to learn how to win the heart of a man the right way. Force is of no use to make or preserve a friend, who is an animal that is never caught nor tamed but by kindness and pleasure. Excite them by your civilities, and show them that you desire nothing more than their satisfaction; oblige with all your soul that friend who has made you a present of his own.—Socrates

Practical Mechanics

By W. H. Raeburn

Article IV. A descriptive discussion of an important subject, simply and clearly stated. Every article of this series should be read and studied by all readers of Canadian Machinery. They are practical and helpful.

THE LEVER.

LEVERS in their various forms enter so largely into the construction of machinery that more than passing attention should be given this mechanism. We have heard of devices invented by those who seek to reach such unattainable ends as perpetual motion and power multiplication, and we can find in some such devices levers used in ways that betray the lack of knowledge on the part of the inventor of the simple law of the lever. Nor do we require to enter the field just mentioned to find mistakes; they stumble into what we might term legitimate machine design occasionally. We have learned from previous articles that there is a difference between force and power, using these terms in their proper sense, yet they are used rather indiscriminately by practical men.

We can exert enormous force by the use of a lever—a man can move many tons—but we never increase power, using this term in the sense of work which we now understand to mean force multiplied by distance.

Proving a Law.

By making a few simple observations we shall find that the following principle always holds good in levers, as indeed in any of the other mechanical powers: The work done at the point of application of the power equals the work done where the load is applied, remembering that in this law friction is ignored, a condition which of course is not met with in practice.

Take a light piece of wood three feet long and balance it at a point one foot from one end, as shown in Figure 1. It is necessary in order to obtain satisfactory results in the present case either to counter-balance the lever before ap-

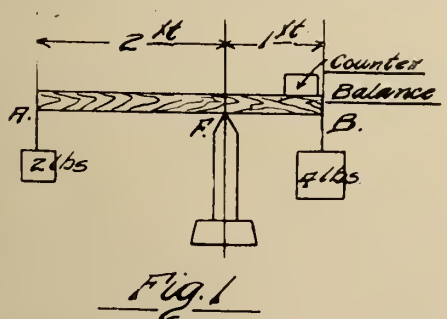

Fig. 1

plying any loads or to take its weight into consideration in our calculations, which latter method complicates matters a little for a beginner, so we shall assume the lever as being properly counter-balanced when supported as shown. Suspend a 2-lb. weight at (A) and it will be found necessary to use one of 4 lbs. at (B) in order to keep the lever in balance. As will be readily understood, the balance is disturbed by the slightest addition to either weight. If the 4-lb. weight descends 1 inch it is clear that the 2-lb. weight will go up 2 inches. This is apparent without mathematical reasoning, which, however useful, we feel constrained to avoid in these articles.

The work done by the 4-lb. weight in decending 1 inch is $4 \times 1 = 4$ inch lbs., and that done at the other end of the lever is $2 \times 2 = 4$ inch lbs., thus demonstrating the law known as the principle of work. A few simple experiments and a little reasoning will teach us that the weights will always be in inverse proportion to the length of the arms of the lever, provided that the lever itself is properly counter-balanced so as to eliminate its weight from the calculations.

Principle of Movements.

We have another and more common method of approaching lever problems,

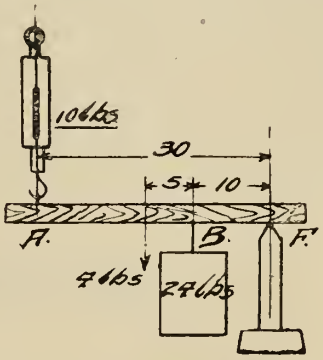

Fig. 2

by way of the principle of moments, which we shall now consider. Our lever is horizontal and the forces represented by the action of the weights act along vertical lines and therefore at right angles to the lever. The moment of the force at (B) with regard to or about the fulcrum (F) is 4 lbs. multiplied by 1 foot equals 1 ft. lbs., and the moment of the force at (A) about the same point (F) is 2 lbs. multiplied by 2 ft. equals 4 ft. lbs.; thus the moments of the two forces are equal and we can reason from this that the moments of the forces tending to turn the lever in one direction must be equal to the moments of the forces tending to turn it in the opposite direction in order to maintain equilibrium. In a simple lever this easily remembered law covers all cases where the weight of the lever is either neglected or counter-balanced—the product of one force and its distance from the fulcrum equals the product of the other force and its distance from the fulcrum. This law holds good in every kind of lever no matter in what relative positions the fulcrum and points of application of the forces are placed or whether the arms of the lever are in the

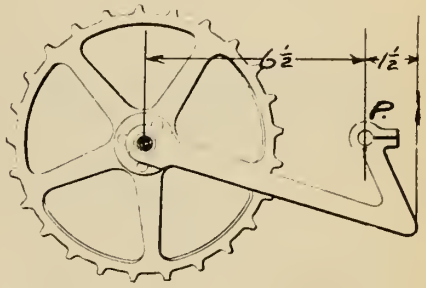

Fig. 3

same straight line or make an angle with each other. We must always see that the distances from the lines of direction of the forces to the fulcrum are measured at right angles to these lines of direction.

In Figure 2 is shown a different arrangement from that in Figure 1. We cannot so easily counter-balance the lever in this case so we shall utilize the experiment to explain how the weight of the lever is taken into consideration. Assume that this weight is 4 lbs. and acts through the centre of the bar or 15 inches from the fulcrum. We have now two forces tending to lower the lever and one tending to raise it, the latter being measured by means of a spring balance. The moments of the two downward forces are $24 \times 10 = 240$ in. lbs. and $4 \times 15 = 60$ in. lbs., making a total of 300 in. lbs. The moment of the upward force at (A) must equal this. The distance from the fulcrum at which this force acts is 30 in., so that

$$\text{the force must be } \frac{300}{30} = 10 \text{ lbs.}$$

These elementary examples illustrate the general principles underlying the use of levers in their many forms. Two of the most common modifications of the lever are the wheel and axle as found in hoisting machinery and toothed gearing

(*Continued on page 86*)

An Innovation in Type-Composing Machines

IT seems almost incredible that after the scores of type-composing machines invented in the past fifteen or twenty years, one can be produced which differs not only in its basic principle from all previous inventions, but also opens up a new field for machine work in the printing industry, and still more incredible that such a machine can be made less complicated than any heretofore built. Yet such are the claims of the little type-casting and composing machine just invented by Messrs. John R. and Gustave A. Pearson.

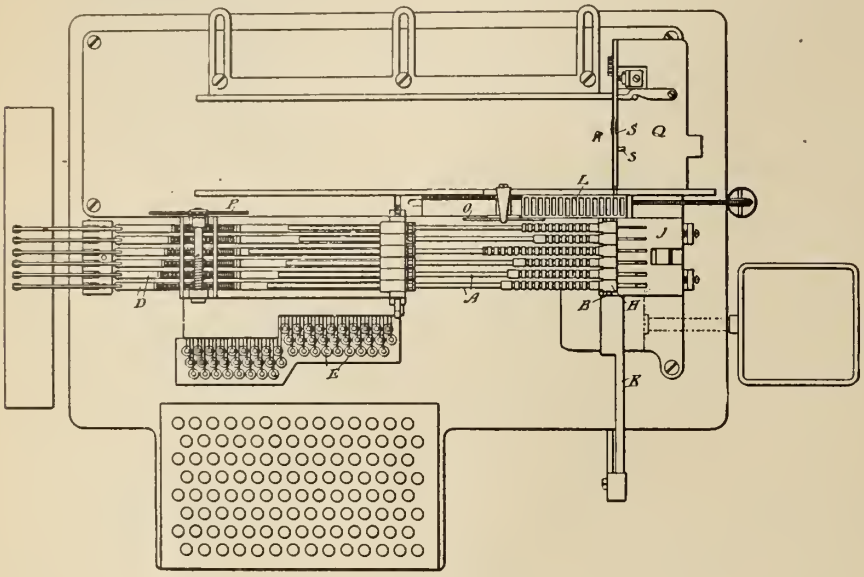

Fig. 1—Front Elevation with the Keyboard Removed.

Aim of Inventors.

The primary purpose of the inventors was to provide a machine which would be used for setting advertisements. This required that the machine should cast single character types and should carry matrices of a number of different fonts. A secondary, though hardly less important aim, was to make the machine so simple and inexpensive that it could be brought within reach of those smaller printing offices which still cling to hand composition, owing to the high cost of the complicated machines now on the market. Undoubtedly the one thing that has stood in the way of simplifying these machines is the custom demanding that all lines of a column should be of exactly the same length, excepting, of course, such breaks as occur at the beginning and end of a paragraph. The operator of a machine obviously cannot determine until after the words of a line have been set how many spaces will be required to justify the line and how thick the different spaces must be.

There are two prineipal methods by which the justifying of the lines has been done. In certain of the machines the matrices are assembled for the entire line with adjustable space bars between the words, after which the line is automatically justified and cast in a single slug. In others a ribbon of paper is perforated in response to the keys of the keyboard, and at the end of each line the width of the spaces necessary to justify that line is automatically recorded by a combination of perforations. The perforated ribbon is then run backward through a separate machine which casts single character type and spaces as selected by the perforations. The purpose of running the ribbon through backwards is to adjust the space-casting mechanism for each line before the casting is done. In neither the line slug nor the individual type machine is any casting done until the keyboard has been operated for at least an entire line. The main objection to the first system is that in making corrections individual types cannot be removed and replaced with new ones, but entire lines must be thrown away and entire new lines composed and cast. The system is further unsuited for ad. composition, owing to the frequent use of two-line type requiring constant variations in the length of the lines. On the other hand the second system is objectionable as it requires two machines and two operators to compose and cast the type matter.

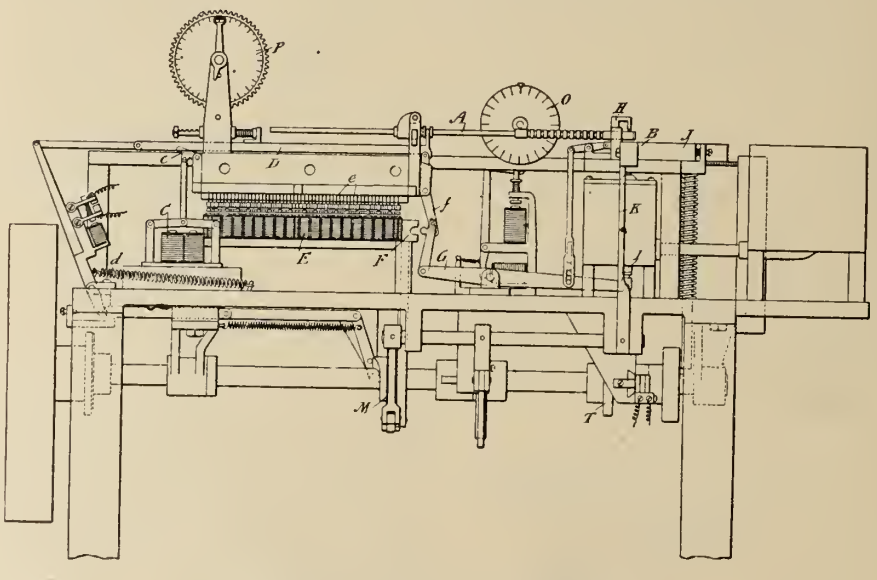

Fig. 2—Plan View of the Complete Machine.

Method of Operation.

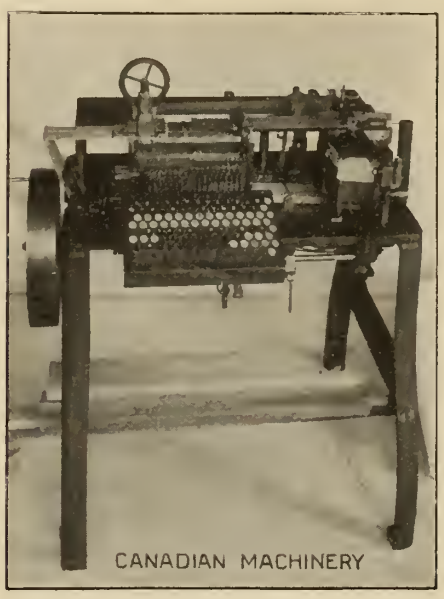
The Pearson invention combines both the casting and composing operations in a single machine and yet it casts single character type. The keyboard operates the casting mechanism directly so that every time a key is struck a corresponding type is immediately cast. This results in a great simplification of the matrix magazine, because the matrices perform their work at once and return to normal position ready to respond to the next touch of the key instead of being held until the entire line has been assembled, justified and cast. On the new machine none of the spaces are formed until all the words of the line are cast and set. But instead of assembling the words in a galley they are kept temporarily in a "word magazine," each word occupying a separate compartment of the magazine. A counter on the machine shows how much the line lacks of being completely filled after the last word has been set, and indicates how thick each space should be to properly justify the line. The key corre-

sponding to the required space is then struck. As the spaces are cast they are successively pushed into the galley with the words in the magazine.

The most interesting feature of the new machine is its multiple font magazine. The matrices are carried on six bars, each bar bearing matrices of a certain unit's thickness. In the machine here illustrated the matrix bars are square in cross section, that is, each bar is formed with four flat faces and on each face a different font of matrices is carried. The number of fonts may be indefinitely increased by increasing the number of faces of the matrix bars. It is probable that the machine will be put on the market with four, six and eight font matrix magazines. At the touch of a lever the matrix bars are all simultaneously turned over to bring a new face into operative position. Thus the setting of advertising matter can go on without interruption no matter how often it may be necessary to change from one font to another.

Details of Machine.

A more intimate knowledge of the machine may be had by referring to Figure 1, which shows a front elevation of the machine with the keyboard removed, and Figure 2, which is a plan view of the complete machine. The matrix bars are shown at (A), and each has its individual mold at (B). The rear bar carries matrices of two units' thickness, and operates over a mold of corresponding width ; the next bar carries three-unit matrices and operates over a three-unit mold, and so on, to the sixth bar, which carries seven-unit matrices. The control of the matrix bars by the keyboard is effected electrically. When a key is depressed it completes the circuit of one of the electromagnets (C), which thereupon withdraws a detent (c) from engagement with a slide bar (D), permitting the latter to be moved forward by a spring (d). The matrix bar which is connected to this slide bar is thereby moved to the mold. One of the magnets (E) is also energized when the key is depressed and it raises a stop pin (c) in the path of a lug on the slide bar, thus stopping the matrix bar with the desired matrix in position over the mold. The casting mechanism belonging to this mold is thrown into engagement with the cam slide (F), by one of the levers (f), which is operated by the forward movement of the slide bar. As soon as the desired matrix reaches the mold, an electrically operated friction clutch couples the cam shaft to the driving pulley. The cam slide (F) then operates to rock the lever (G). A guide clamp (H) and an injector (I) are operated by this lever, the former serving to position the matrix to accurate register with the mold and clamp it firmly in place, while the injector which passes through the pot injects molten metal into the mold. The molds are all formed in a common channel which is partitioned off by means of movable walls attached to a block (J). These walls are withdrawn as soon as the type is cast, and the ejector pushes the type laterally along this channel to a compartment of the "word magazine" (L). The various parts are then returned to their normal positions, the matrix bar being withdrawn by a cam M. The entire operation is performed at a single turn of the cam shaft, which thereupon automatically releases the friction clutch and comes to rest. Thus at each touch of a key the corresponding type is immediately cast. At the end of each word a key is struck which moves the word magazine



New Type Composing Machine.

to bring a new compartment in line with the mold channel, and when all the words of a line are assembled the magazine is returned to its original position with the first word in line with the channel. Thereupon at each touch of the space key the magazine is moved forward to bring the words successively in the path of the ejector (K). By means of a simple device the travel of the injector is increased so that as the spaces are cast they are pushed with the words into the galley (N). Spaces may be cast in any of the molds, and the dials (O) and (P) inform the operator at the end of each line which key to strike and how often to strike it in order to properly justify the line.

To prevent the type from falling over as it is pushed into the galley, it is received in a channel formed between the end block and the fence (R), while a filler piece (S) bears against the end of the line. An adjustable pin (s) on this filler piece springs a latch when the last word is moved into the line, connecting the end block and the fence with their cam (T). This latter lowers the fence and causes the end block to push the assembled line of type down into the galley far enough to permit the assembling of the next line.

It is expected that the new machine will be found very useful in the ad. rooms of our large daily newspapers, and also for composing all classes of matter in the smaller printing offices. It is designed to average about 4,000 ems per hour, though there seems to be no reason why it should not be speeded up to a very much higher figure

EXTENDING THEIR PLANT.

The firm of Sheldon & Sheldon, Galt, Ont., are steadily building up their business to one of large proportions. The efficient manner in which the many large contracts have been carried out by the firm has been the foundation for a steadily increasing business. In consequence, it has been necessary to increase their manufacturing capacity, and plans and specifications are about complete for a large extension to, and the remodeling of, the present plant.

At present, the offices and drafting rooms are in a building separate from the main plant, as is also the foundry. According to the plans for the extension, the offices will be in the corner of the extension, and the present office building removed. The extension is to be a two storey building, 160 x 64 feet, brick and slow-burning timber construction. A temporary wall is to be placed at the end of the new building so as to facilitate further extensions.

The equipment of the plant is to be modern in all detail, including the remodeling of the present plant. This equipment will include traveling electric cranes.

This extension has been contemplated by the firm since the Fall, and during that time plans were made for a new building; but since then new plans have been formed providing for a much larger building than the first.

It is hoped that the new plant will be in running order by March, and at that time a complete description will appear in Canadian Machinery.

"If there were not frequent disappointments, there would be no constant desire and reaching out for better things—no progress, no advancement."

Practical Questions and Answers

Size of Fire Bricks.

Ques.—In what sizes are fire bricks made?

Ans.—There are five regular sizes of brick, besides the different sizes of jamb, wedge, key, arch, skew and circular. The rectangular shapes are: The 9-inch straight, 9x4½x2½ inches; the soap, 9x2½x2½ inches; the checker, 9x3x3 inches; the 2-inch, 9x4½x2 inches; and the split, 9x4½x1¼ inches.

* * *

Punched Plates.

Ques.—When iron and steel plates are punched, there is a certain loss of tenacity owing to the bruising of the metal around the punched hole. What is this loss of tenacity in plates up to ¾-inch?

Ans.—A report made some time ago to Lloyd's Committee contained the following table showing the depreciation in the tenacity of the plate when punched, and when neither reamed nor annealed:

Thickness of plates.	Material of plates.	Loss of tenacity p.c.
¼	steel	8
⅜	steel	18
½	steel	26
⅝	steel	33
¾	iron	18 to 23

In plates less than ¼-inch there was no appreciable loss of tenacity, and it was found that if the plates were reamed out to about ¼-inch greater diameter, the plates were as strong as if the holes had been drilled in the first place. Annealing will restore the plates to their original tenacity.

* * *

Hand vs. Machine Riveting.

Ques.—What advantages has machine riveting over hand riveting as regards efficiency?

Ans.—In a report to the Institute of Mechanical Engineers, made by Professors Unwin and Kennedy, the following points are brought out:

(1) That the shearing resistance of rivets is not greatest in joints riveted by the greatest pressure.

(2) That the ultimate strength of joints is not affected to any appreciable extent by the mode of riveting.

(3) That the most serious defect of hand riveting as compared with machine riveting consists in the fact that in hand-riveting visible slip commences at a comparatively small load, that giving those joints a low value as regards tightness, and possibly also rendering them liable to failure under sudden strains after slip has once commenced.

From tests made by Professors Kennedy and Unwin it was shown that the load at which visible slip started was on an average about twice as great for hydraulic riveting as for hand riveting.

Thus to sum up, the hand riveting is quite as good as hydraulic riveting as regards strength of joint, but for tightness the hydraulic riveting is much superior.

* * *

Thermal Efficiency.

Ques.—What is meant by the thermal efficiency of an engine?

Ans.—The thermal efficiency of an engine, gas or steam, is the limiting efficiency of the engine, and which is never reached because all the heat units that enter the engine in the steam or other gas cannot be converted into useful work because of the loss by radiation, leakage, condensation, etc. The thermal efficiency is expressed by the following formula:

$$E=\frac{T-T'}{T'}, \text{ where}$$

E=thermal efficiency,

T=absolute temperature of the steam or other gas as it enters the engine; and

T′=absolute temperatare of the exhaust steam or gas.

An example will make this plain:

Prob.—To find the thermal efficiency of a steam engine running under a boiler gauge pressure of 150, and exhausting into a condenser, where the vacuum gauge reads 26 inches of mercury.

Sol.—The temperature of steam under a gauge pressure of 150 pounds per square inch is 365 degrees F., and the temperature of steam in a 26-inch vacuum is 127 degrees F.

$$E=\frac{T-T'}{T}=\frac{(365+461)-(127+361)}{365+461}$$

$$=\frac{826-588}{826}=0.28 \text{ nearly}$$

=28 per cent.

* * *

Use of a Booster.

Ques.—What is an electric booster, and for what is it used?

Ans.—A booster is an electric machine inserted in an electric circuit for the purpose of raising the voltage. A booster may be run by motor or otherwise. The machine is used extensively on three-wire lighting systems and street railways, where a constant potential is required. The drop in potential from the generating station to the end of the feeder may be compensated for by a booster. The field and armature of the booster are in series with each other, and with the feeder, and thus the whole current passes through the armature. The E. M. F. of the booster will be proportional to the feeder current, and can be designed so as to increase the line voltage to its original value.

Boosters are also used in central power stations of electric railways to raise the voltage supplied to the feeders connected to the distant sections of the line; and they are used, too, in connection with electric elevator service, where the elevator motors are supplied from the same generator as the lights in the building. The intermittent excessive currents demanded in the elevator service in the starting of the motor produces wide fluctuation of voltage, and a booster is often inserted in the circuit to raise the voltage at the necessary times.

* * *

Hydraulic Forging.

Ques.—Is forging ever done by hydraulic pressure?

Ans.—The hydraulic forging press is often used to produce heavy forgings. When a quick acting steam hammer is used to forge a large mass of metal, the surface of the forged mass tends to absorb nearly all the effect of the blows, whereas when the equally powerful but slower acting hydraulic press is used, there is time for the pressure to be transmitted throughout the metal.

* * *

Efficiency of Centrifugal Fans.

Ques.—On what properties of the centrifugal fan, and on what operating conditions, does the efficiency depend?

Ans.—Very definite experimental results have not been obtained along these lines, but from experiments that have been conducted it would appear that the only two things on which the efficiency of the fan depends appreciably are the shape of the spiral casing and the speed at which the fan is operated. Neither the diameter of the fan nor the width nor the shape of the blades seem to affect the efficiency of the fan.

There are two shapes of spiral cases in use, the first being a large spiral in shape, beginning near the point of cut-off, and the second a circular casing, extending three-quarter way around the circumference of the fan and ending with a short spiral. Fans having the first form of casing nearly always give high efficiency.

The speed giving the highest efficiency seems to be between 5,000 and 6,000 feet per minute. Above 6,000 feet per minute the efficiency drops off rapidly.

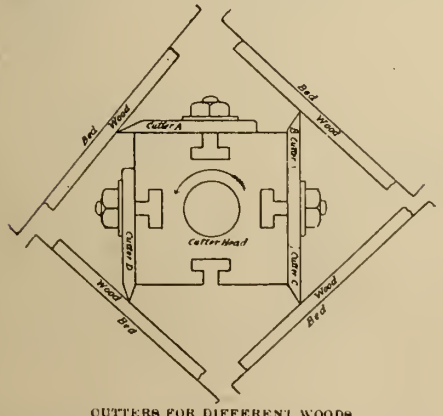
Reviews of the Month

OPINIONS AND STUDIES WORTH NOTING

METHODS FOR CUTTING DIFFERENT WOODS.

THE accompanying sketch almost explains itself, but a few words may make it plainer to some readers. It shows four different methods employed to cut hard and soft woods. (A) is the ordinary cutter found in every factory where wood-cutting is done by machinery, and is about the simplest and best cutter yet devised for all kinds of work. The part below marked "wood" shows the position the cutter has while in the cut. One can readily see the amount of hook or pull this cutter has on the grain, which is very bad in some woods, tearing up the grain in such a manner as to put this cutter out of the question for economical use in good, smooth work in hard or cross-grained wood.

(B) is the same cutter turned on its back and the edge beveled slightly on the face, or that side which now is the back. This is done in order that the edge be stiffened sufficiently so it will not turn over or back as readily as if this were not done. This manner of using cutters is only a makeshift at best, and would never do for heavy work, but it is a very handy way to work when one has only a few pieces to run and it will not pay to make or buy better cutters with which to do the work. Note the position this cutter has in the wood while working. It is almost needless to say that a cutter used this way will not tear up the grain. This cutter takes about twice as much power to do a given piece of work as does the one marked (A). Many milled cutters are used in this manner, to run



CUTTERS FOR DIFFERENT WOODS.

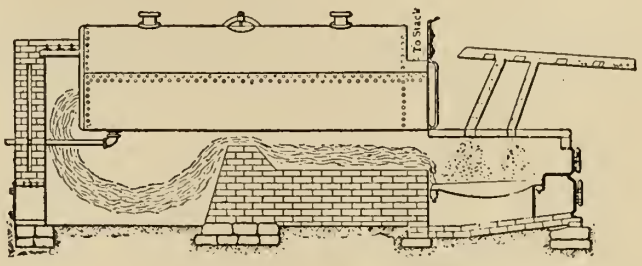
mouldings, the milling being done on that side which is now shown as the back, and the cutter ground straight on the bevel only. By this method the shape of the moulding remains the same always.

(C) is the same cutter as (A) and (B), but used in a different manner. As will be seen, this cutter is set the same as (A), but on the opposite side of the head, thus giving it an entirely different and directly opposite cut when in the wood. This method is only good for a light cut and does very nice finish work where the grain is knotty and there is danger of pulling out otherwise. This method of fastening a cutter may be put to another use—that of a scraping machine. All that is necessary is to sharpen the cutter to a good edge with the whetstone, then take a round instrument and turn the edge inwardly, the same as a bench man would turn the edge of his sand-scraper, except in this case the cutting edge is only turned toward the face to form that hook so necessary in scraping. In scraping the head does not revolve, but is set at the desired angle, fastened in that position and the material fed against the cutter in the same way a man at the bench draws his scraper against the wood, but in this case it is the wood going against the scraper.

(D) is a kind usually used for cross-grained, hard and knotty stock, which is liable to tear out while dressing. Note the way this cutter is ground ; the cutting edge is ground both ways. The effect of this is the edge has very little hook to pull the grain up while in the cut compared with that shown at (A), hence it is better adapted for hard, knotty and cross-grained woods than (A). Its good points over cutters (B) and (C) are that it has a very stiff edge which can be changed to suit the nature of the stock being worked. The reader will readily see that this cutter is well adapted for ordinary use where the work is done in small quantities. The arrow indicates the direction in which the head revolves.—Wood-Worker.

BURNING SAWDUST.

A FURNACE and boiler setting like the one shown in the diagram is an excellent arrangement for burning sawdust. The boiler setting itself is like that usually used in a horizontal boiler, but the grates are in an oven or projection built in front of the boiler instead of being under it. The oven is



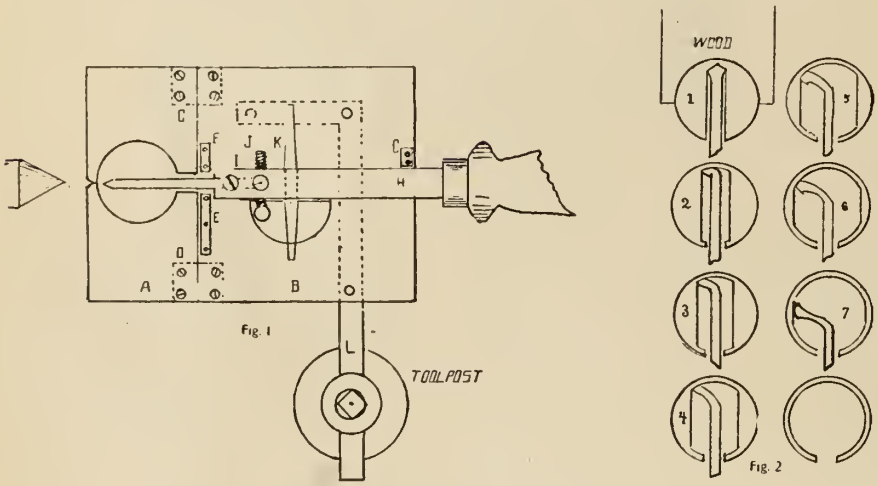
SETTING FOR BURNING SAWDUST.

about 10 feet long and should be full width of the boiler, or if convenient, 2 feet wider than the boiler is preferable. The grates should have $\frac{1}{4}$-inch openings. The sawdust, brought by a mechanical carrier of some kind, is dropped through two chutes onto the grates and lies in two cone-shaped piles that cover the entire grate surface. The fire should be started with shavings or other dry material and will burn principally around the edges where the draft will force itself up through the fuel. When well ignited the surface of the cones will be covered with flames and the sawdust will burn furiously. The supply of sawdust may be regulated by slides in the chutes. It is not necessary to use a firebar ; simply fill up with the fuel and let it burn. To bank the fire at night, fill the furnace well up to the top with the sawdust and level it off, close all doors and the damper and let it alone.—Power.

HOW TO TURN A HOLLOW BALL.

AS most machinists are familiar with the turning of a sphere by means of the compound rest, it will not be necessary to go into details. Assuming we have a ball 1 inch in diameter, and wish to bore out the inside so as to leave a shell 1-16-inch in thickness : A piece of hard wood is clamped in the chuck and the end turned out cup-shaped

(Figure 2, first cut), so that it will extend a trifle over the centre line of the ball. A little chalk rubbed into the wood will help to hold the ball firmly in position. Now the tool rest (Figure 1) is clamped in the tool post by an L-shaped piece of stock (L), riveted to the bottom, just high enough to allow the tool, when resting on the support, to come to the centre of the ball. The tool rest is made of two pieces of sheet metal, (A) and (B), which are hinged together on the line (CD), allowing (A), which is only used as a gauge for setting the tool to be folded down; (E), (F) and (G) are guides for the tool holder, the former two also serving as stops. The tool holder, (H), is made of $\frac{3}{8}$-inch square stock, having a $\frac{1}{8}$-inch hole in the end to insert the tools, which are held by means of a set-screw, (I). Back of this is the guide screw, (J), a piece of 3-16-inch stock is fastened to the end just long enough to reach down into the semi-circular aperture cut into (B). (K) is a crosspiece fastened to the bottom of (H) to insure a wide bearing on the tool



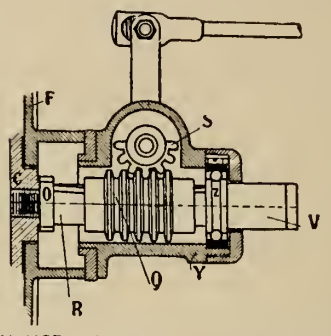
Method of Turning Hollow Ball.

rest. To adjust the tool rest in position we measure the distance between the aperture cut in (A) and the line (C-D), say $\frac{1}{4}$-inch in this case. Now the gauge (A) is folded down and the carriage moved towards the ball until the line (C-D) is $\frac{1}{4}$-inch away from the nearest point of the ball and locked there, then the cross slide is moved to bring the centre line of (H) in line with the lathe centres. If there is any difference between the diameter of the ball and the hole in the gauge plate (A), allowance for such difference must be made in adjusting the tool rest. Now the carriage is backed, the gauge is raised on a level with (B) and the first tool in the shape of a flat drill inserted in the tool holder in such manner that when the tool holder is up against the stops (E-F-G) the point of the drill will be 1-16-inch away from the edge of the hole (Figure 1). Turning the gauge plate down, the carriage is again moved up to the stop and locked there, the ball having been previously centred, we now take the first cut with the tool up to the stop. The chips may be removed by blowing into the hole with a blowpipe. Back up the carriage again and turn up the gauge plate and insert the second tool and turn the guide screw (J) to such position that both cutting edges of the tool will be 1-16-inch away from the edge of the hole in the gauge at either end. Once more the gauge is folded down, the carriage moved up to the stop and we take the second cut. In each of the subsequent cuts another tool must be inserted, shaped to fit that part of the circle to be cut away, and the guide screw (J) must be adjusted to the length of the cut.—Popular Mechanics.

THE MAGNETO IGNITER.

FOR automobiles, motor boats, and gas engine practice generally, the coming of the magneto ignition is apparent, and although its progress has been slow, it has been sure, and during the coming season many makers will give buyers the option of having either magneto or battery ignition, and in some cases both systems will be fitted, the magneto being used for doing the work while running and the batteries for starting up by the switch, the battery adjunct having this advantage, that the operator is able to start up his motor by merely moving over a switch, which saves a lot of cranking, and also dismounting from the car.

Figure 1 gives a view of the advance movement of the Lacoste magneto, while another well known magneto is the Eisemann. As shown in the diagram (Figure 2), the Eisemann igniter consists essentially of a magneto and a transformer. The primary of the latter is constantly connected with the terminals of the former, and a short-circuit interrupter, which also is connected with the terminals, permits at will of sending the current of the magneto into the transformer. When the interrupter is closed, the magneto is in short circuit, and its current attains its maximum degree of intensity and power. If, at this moment,



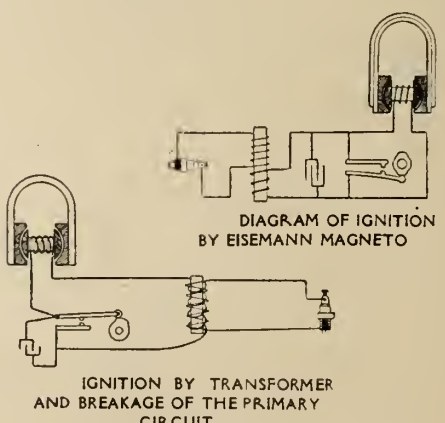
ADVANCE MOVEMENT LACOSTE MAGNETO

F. Supporting Plate. C. Commutator End. O. Timing Gear. Q. Sliding Sleeve. R. Helical Grooves. S. Advance Gear. V. Carter. Y. Driving Shaft. Z. Ball Bearing

Fig. 1.

the interrupter be opened, it will be possible for the current to circulate only through the primary of the transformer. The result of this is that when the current reaches the transformer, a supermagnetization of the iron core is produced, greater than that which would correspond to the current normally developed by the magneto unprovided with this arrangement.

Referring to the diagrams of high-tension ignition apparatus, we find that both break the primary current in order to produce in the coil the variation of magnetic flaw which gives rise in the secondary to the high tension that is utilized. But when a current is broken by separating the two contacts of the breaker a spark is produced between them. The wear resulting from this spark is abolished by the use of a condenser. Here are shown two other methods by which ignition is obtained



IGNITION BY TRANSFORMER AND BREAKAGE OF THE PRIMARY CIRCUIT

Fig. 2.

with a magneto. In the diagram of Figure 4, the upper left-hand view shows the spirals of the winding being traversed by the magnetic flow emanating

from the magneto, while the view to the right shows the flow a minimum. It may be seen that the flow will change direction twice per revolution. The laws of induction teach us that there will, consequently, be produced in the armature a variable periodical electromotive force presenting a maximum at every half revolution. If we close the exterior there will correspond a maximum of currents to every maximum of electromotive force. We shall, therefore, be able to obtain two sparks per revolution of the magneto. This condition determines the rotary velocity of the magneto with respect to the motor. If the motor is a four-cylinder one, such velocity will be that of the motor, since four sparks are necessary at every two revolutions of its shaft. If it is a two-cylinder one, a control, reducing the velocity one-half, may suffice. Finally, if the motor has three cylinders, it will require three sparks at every two revolutions. It will suffice for the motor to make one revolution and a half at every two revolutions of the mator. The current-breaker placed upon the magneto and controlled by a cam causes an abrupt emission of the current of the magneto into the primary of the transformer. This impulsion of current gives rise to a high-tension current in the secondary, and this is automatically sent to each of the spark plugs by a distributor connected mechanically with the magneto in order to operate synchronously with it.

The inductor of the magneto shown in the lower view is formed of three pairs of horseshoe magnets, placed side by side. These magnets are secured by screws to cast-iron polar pieces, the object of which is to distribute the magnetic flow uniformly upon the armature.

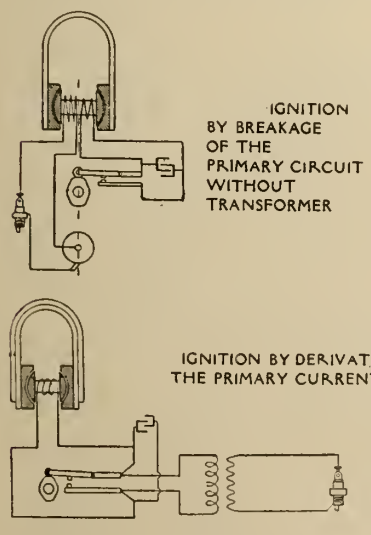


Fig. 3.

The nature of the steel and the temper to which the magnet is submitted after manufacture are the sole guarantees of the duration of the magnets. They assure them a greater resistance to the external causes that may bring about their demagnetization, such as heat, vibration, shocks and the very near vicinity of powerful electromagnets or alternators.

STATIC ELECTRICITY IN ORE SEPARATION.

FOR nearly five years electrostatic ore separators have been in successful use. This is true, at least, of the Blake-Morscher machine, of which more than forty are in operation. When this machine was first introduced commercially, its use was largely confined to those ores whose constituent particles differed widely from each other in conductivity.

Another process developed by this company, and one not widely known, is that which depends for its operation on the specific inductivity of various materials. In its simplest form, shown in the annexed illustration, the apparatus now in use consists of a hopper and feeding device (A), charged poles (B) and (B1), and receptacles (C), (C1), (C2) and (C3).

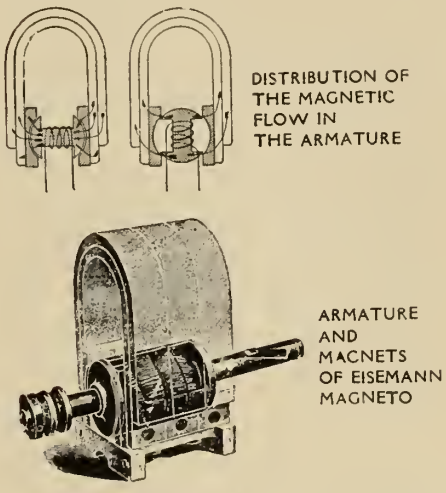

Fig. 4.

The poles (B) and (B1) are usually highly charged with electricity of opposite sign, but not necessarily of the same potential. When a stream of ore particles is dropped through the field between the two poles, the particles are urged out of their original path and into different directions, with varying degrees of force, depending on differences in their specific inductivity ; the several minerals fall, each into its own receptacle at the bottom. Nothing could be much simpler, yet the thing is positive, and the results are remarkable.

With such an apparatus it is possible to separate substances independently of their conductivity. As an example of materials of approximately equal conductivity fluorite may be separated from quartz or barite, barite from blende, and feldspar from corundum.

It must be evident that this enormously widens the field of the electrostatic process ; and, when used in connection with conductivity separations (where the conductivity is either natural or produced artificially), it gives a range covering almost all known minerals.

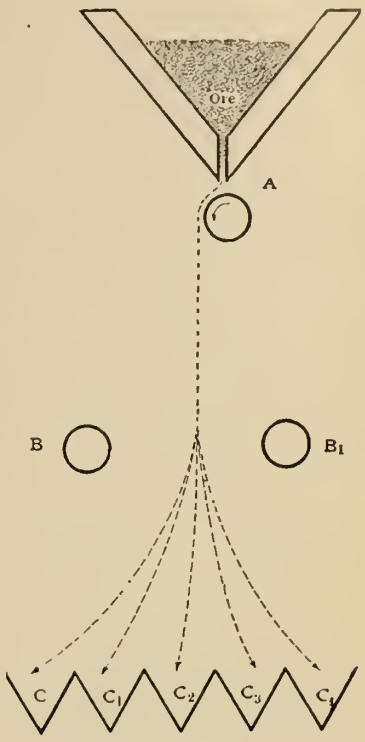

Diagram of Apparatus for Ore Separation.

The electrostatic generator has also been made closely to approximate the dynamo in reliability. The machine of the laboratory or of the physician, running uncertainly a few moments at a time, has given place to mechanically strong and powerful mica-plate generators, running continuously night and day, in damp and dusty mills, with ordinary help.

As now used by the Blake Company, all brushes and other moving contacts are abandoned ; the field-plates are in static shunt with the generating rotors, so that the machines are self-exciting. The ozone and nitrogen compounds which are continuously formed are removed as fast as generated, by a forced draft of hot, dry air, which also prevents all moisture deposits, so that the machines are now independent of atmosphere or altitude.—Engineering and Mining Journal.

CONCENTRATION.

" When you set out to do anything, never let anything disturb you from doing that one thing. This power of putting the thought on one particular thing, and keeping it there for hours at a time, takes practice, and it takes a long time to get into the habit "—Thomas A. Edison.

BOOK REVIEWS

Choosing a Career, by Orison Swett Marden, an outline of the possibilities in life. 481 pages. Indianapolis: The Bobbs-Merrill Co., publishers.

No one can peruse the pages of this book without catching, somewhat, the enthusiasm and inspiration of the author in his logical outline of the different considerations to be taken into account when choosing a career. Throughout, the thought is kept prominent that one should engage in a vocation at which he will be happy, the latter being paramount, compared with which the acquisition of wealth is nothing. The keynote of this is expressed in the author's words "Other things being equal, try to enter a calling which will have an uplifting influence upon your health, which will be a perpetual tonic to you, not a depressant." Without health one cannot achieve success.

The author states that it is a mistake to think that everyone has a decided bent for a particular vocation, as many people are so finely balanced in their mental make-up that they can follow one of several callings with equal facility.

Not only should this book be read by every young man and woman, but by every parent anxious for the welfare of his or her offspring. It is a gem sparkling with sage advice and up-lifting suggestion, and is, at the same time, interesting and fascinating. It broadens one's vision of life, inspires to better effort and offers practical assistance to those in doubt as to the future. To every reader of Canadian Machinery, "Choosing a Career" is heartily recommended.

Machine Tools and Workshop Practice, by Alfred Parr, instructor in fitting and machine shop and forge, University College, Nottingham. A practical work for engineering students and apprentices, 444 pages, 510 illustrations. Price, 10s. 6d net. London: Longmans Green & Co., 39 Paternoster Row.

At the outset the author announces that this volume is the result of an increasing demand for technical instruction by engineering students and apprentices, and with this in view the subject matter has been prepared. For either the student or the skilled mechanic, this volume is exceedingly valuable, covering, as it does, the entire range of machine shop practice, a commendable feature being the numerous drawings that assist the descriptive matter to no small extent. The opening chapter on "measurement" gives the reader an idea of the wonderful precision attained in present day mechanical practice. Following a chapter on "Marking or Laying out Tools," is one devoted to the metals used and their properties. The different machine tools are then described and the modern practice associated with each explained. The chapter on cutting tools is one of the most valuable. Going somewhat out of the machine shop, forge shop tools and hydraulic machine tools are dealt with, when the subject of transmission of power is gone into in some detail. The last chapter is devoted to methods of working.

This volume is meritorious from a mechanical and technical standpoint and will prove of considerable value to the class for whom it is designed. In a subsequent edition it might be suggested that the quality of the illustrations be improved, as many of them are below standard.

Manual of Mechanical Drawing, by Phillip D. Johnston, superintendent and mechanical engineer, West Point Foundry. A simple and thorough groundwork in modern drafting room practice; covered. New York: David Williams Co., publishers . Bound in cloth. Size, 7 1-2 by 9 1-2 inches. Price, $2.00.

A good many books on mechanical drawing have been issued from time to time, each with its strong points and its weaknesses, but the book on mechanical drawing under review has approached a standard of excellence against which little criticism can be made, and in favor of which there is every chance of appearing partial. It covers thoroughly the ground work intended for those studying or practicing mechanical drawing, and serves as a means of self instruction for working mechanics, apprentices and students generally. The book is concise and at the same time broad in its scope. The study of this on the part of a student would give him a thorough insight into modern drafting room practice.

The Practical Engineer's Pocket Book and Diary for 1906. Manchester Technical Publishing Co. Price, 1s. 6d.

This is a companion to the Electrical Pocket Book published by the same firm. It is, however, much more detailed than the other, containing nearly 600 pages and takes up the subject from the viewpoint of the mechanical engineer, being primarily arranged for his benefit. However, it has a claim on every metal working mechanic as well as those associated with the generation of power.

Modern Machine Shop Construction, by Oscar E. Perrigo, M.E. Nearly 400 large quarto pages; over 200 engravings; price $5. Dealing with the equipment and management, as well as the construction, of the modern machine shop. New York: Norman W. Henley Publishing Co., 132 Nassau street.

This book has been designed for the practical and everyday use of the architect who designs, the manufacturer who builds, the engineers who plan and equip, the superintendents who organize and direct, and for the information of every stockholder, director, officer, accountant, clerk, superintendent, foreman and workman of the modern machine shop and manufacturing plant.

Modern machine shop construction has entered the field just at a time when such a volume was most needed, and the excellent manner in which the author deals with the subject speaks well for his intimate knowledge of everything connected with the machine shop and manufacturing plant. It fills a place for those contemplating building, as well as for manufacturers already long established. It is divided into three parts, the first of which deals with the construction from the choosing of the site to the complete equipment of the plant. Different methods of building are dealt with, followed by the matter of a power house, heating ventilating and lighting systems, as well as other adjuncts of an up-to-date plant. In the second part the equipment is discussed, the buildings and apartments being first arranged and allocated. Each of these receives attention, and the machinery necessary to equip it thoroughly is mentioned. An important feature here is the transportation problem, which is fully discussed. The management is taken up in part three, divided into capitalization, manufacturing and selling. This feature of the book is one that receives too little attention at the hands of manufacturers, and yet is one of the most important considerations that go towards making manufacturing a success or a failure. The important subject of cost keeping is treated in a most systematic manner, different methods and their operations being fully developed.

The volume under review should find its way into every manufacturing plant and industrial concern aiming to keep abreast of the times.

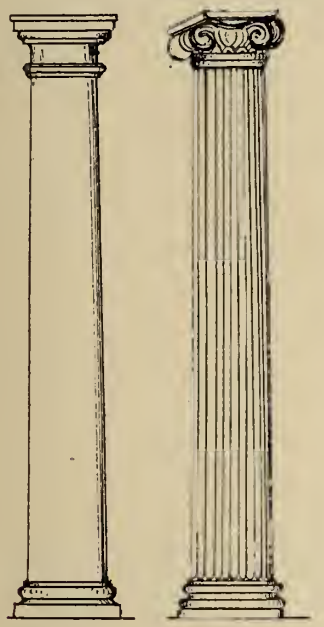
Construction and Improvement

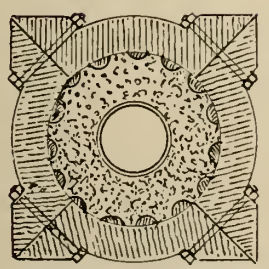
General Construction *Contractors' Supplies*

THE CONCRETE COLUMN COMING.

OUR factory buildings and manufacturing plants are not intended to be things of beauty or ornaments to the neighborhood, being designed, as they well should, with an eye to economy. At the same time a little more thought and attention as to appearance would go a long way towards making

Columns made of Concrete — Caps & Bases of Cement





— Sectional view of mould — for fluted Shafts —

attractive and more desirable the district in which they are located. There is no reason why the fronts of industrial concerns should not be designed with the same artistic effect as those of banks and public buildings, now that the adaptations of cement and concrete are so manifold, and the cost compared with stone so low.

One of the means to this end should be found in the concrete column now being made to considerable extent. According to Cement and Engineering News, from which the views shown of molding concrete columns are taken, the concrete column must and will eventually displace those of stone and wood. A wooden column fluted, 20 feet high by 30 inches in diameter, will cost at the factory $85.00, with transportation charges extra. The form for molding such a column in concrete will cost $100. Assuming only four columns made from this form, the cost comes to $25 each. From actual experience four columns were made from a form at a total cost of $50 each, a saving of $35 a column over wood, or $140 on the four. Six other columns were subsequently erected of concrete on the river front of the same building, using the same form. This reduced the price of the form to $10 per column, while the concrete and labor of placing into the form was $25 per column, or $350 for the ten concrete columns complete, as against $850 for wooden columns, showing a net saving of $500 on the ten columns in favor of concrete.

—

LIGHTNING AND MODERN STRUCTURES.

IT is a well known fact that any constructions made entirely of iron are practically immune against the effects of lightning, as the amount of electricity accumulated in the case of a lightning stroke is allowed to distribute itself over the large surface of the roof, and to flow off to the earth at many places with greatly reduced intensity. Conditions are quite similar in connection with buildings made entirely of armored concrete, as the discharging current will find the roofing iron and distribution rods of an armored concrete roof, struck by lightning, a good conductor of electricity, so as to flow off to the more substantial girder iron with which the roofing iron is connected by wire meshes. Now, as experience has shown lightning not to be discharged to the earth in a concentrated jet from the place of striking, but to have a tendency to distribute itself to all sides, if possible, the electricity will be diffused throughout the roof traversed by a network of iron rods. The electricity being greatly reduced in intensity, will have an excellent opportunity of flowing off to the ground through the round irons inserted in armored concrete columns, thus being communicated to the foundations of the current column, which in turn transmits it to the ground. This shows that neither artificial lightning arresters nor their parts will be required in connection with any construction consisting entirely of armored concrete.

Steel Smoke Stacks for Mills

By F. C. Douglas Wilkes, B.Sc.

IN the place of brick stacks for saw mills and similar plants that are isolated, steel stacks are almost invariably used. They are much cheaper than brick and more easily erected, and last the life of the mill, if properly erected in the first instance, equally as well as a brick chimney. Of course a chimney of brick will outlast one of steel as the elements do not make such

I.—Stack Being Erected.

inroads upon brick as upon steel, but this long life is of no material advantage when the cost of each is compared, because the situation of the mill itself is liable to be changed and moved nearer to the timber limits long before the brick stack is beginning to show any signs of dilapidation.

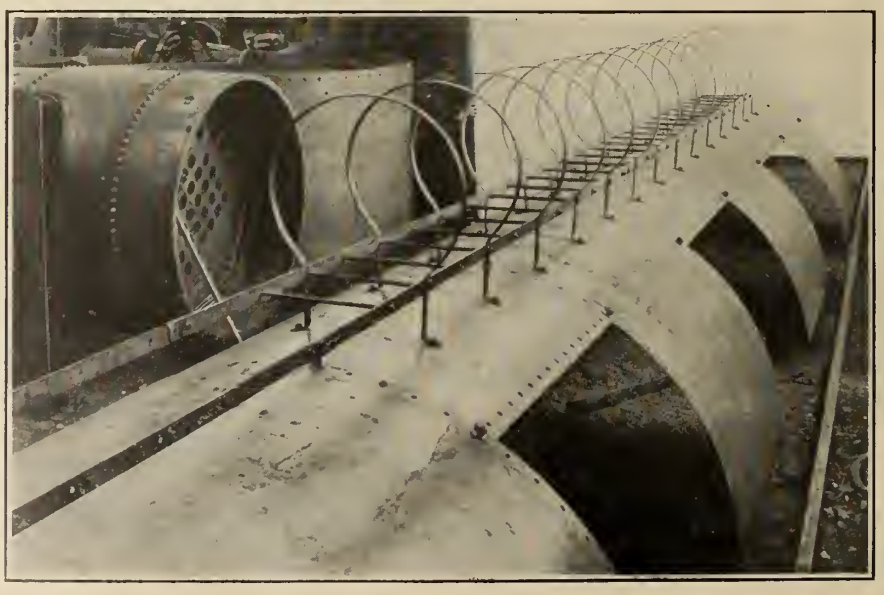
Steel stacks are manufactured and shipped to the mill site in two ways. One way is to make the stack up into lengths, like the lengths of a huge stove pipe, and these are forwarded in this shape to be erected. The pieces are riveted together into one length while on the ground near the spot where it is to be put up. A stout mast is manufactured by splicing lengths of timber together, if one piece of suitable length is not obtainable, and this is set up as close to the stack base as possible. The length of the mast is dependent on the length of the stack to be erected and should be as long as half the stack plus the height of brickwork, plus six or seven feet to clear the tackle when stack has been hoisted high enough to drop into place, plus one foot for the guys above the tackle. The guys should be made of rope that has been used so that most of the "stretch" is out of it, and then when the mast is guyed it is not likely to sag one way or the other when the weight of the stack comes on it. The stack is slung just on one side of its centre by an endless chain sling which is just long enough to go round the stack and permit the hook of the hoisting cable to be hung to it. The position of the sling should be against the first row of rivets off the centre. A guide rope is fastened to the end of the stack to be near the ground and it is then ready to be hoisted into place. Any suitable means of hoisting may be used providing it is of sufficient strength to do the work. Photo No. 1 shows a stack being erected in this manner. This method is used whenever the size of the stack makes it practicable, but in the erection of very large steel stacks say of 100 feet in length and six feet in diameter this method would hardly do on account of the immense weight and the unwieldiness of a stack of this size.

Then the plates are sized and punched at the manufacturer's and tried as for fit, etc., before being sent out. Photo No. 2 shows a portion of a stack six feet in diameter and one hundred feet in length, as it is being tried in the shop. In this stack there are three plates to a "course." The bottom plates are $\frac{1}{4}$ or $\frac{3}{8}$ of an inch thick, the midway plates are 3-16 or $\frac{1}{4}$-inch thick and the top plates are $\frac{1}{8}$ or 3-16-inch thick. The ladder is provided with guard rings, and is also built in sections.

Materials of Construction.

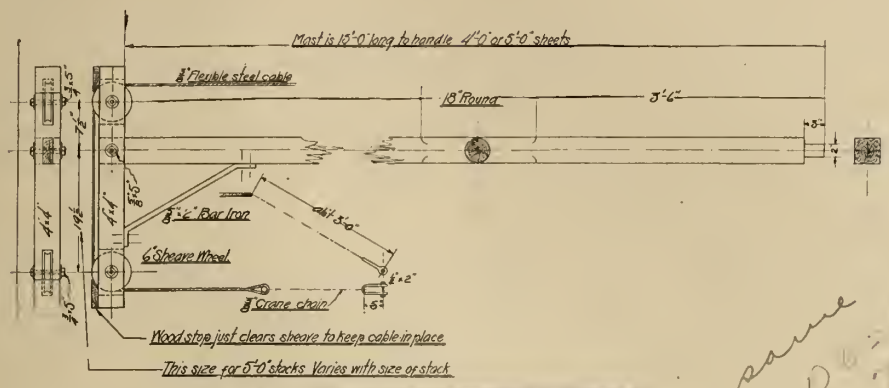
When the sections are all marked and at the mill site, the materials used and the procedure of erection are as follows: Materials used—One crane, suitable length of cable, one winch or hoisting engine, one piece of hard wood to support crane, sufficient planking for platforms and sufficient material for scaffolding to the length of the stack, and if the rivets are driven hot a small portable forge is required. The crane as shown in Figure 1 consists of a piece of hard wood 4 by 4 inches, about 15 feet long. Across the top of this is a shorter piece of the same stuff 3 feet 3 inches long, making the arm of the crane, which carries the sheave wheels. The centre of one wheel is about 20 feet from the centre of the mast and the centre of the other is about $7\frac{1}{2}$ inches from centre of mast. The arm is fastened to the mast by being tenoned through it and bolted. It is supported on its longer end by a piece of bar iron $\frac{5}{8}$ by 2 inches. The crane arm is morticed to receive the sheave wheels which run on bolts of suitable strength used as axles. Bolts $\frac{3}{4}$ inch in diameter are strong enough. Two wooden blocks are placed at the end of the arm for the purpose of keeping the cable always on the sheave wheels. The crane has its foundation on a piece of hard wood 3 by 12 inches on the second stage of the scaffolding and is turned where it passes through the platform above.

The cable is of flexible steel wire $\frac{3}{8}$ inch diameter. This should be long enough to reach from the ground to ten or fifteen feet above the highest part of the stack when erected and thence to the bottom of the stack and to the winch. It is supplied on the end with an eye to which are fastened two pieces of $\frac{3}{8}$ chain. Each piece of chain is about 3 feet long and is supplied at the free end with a clevice of about 5-inch centres which is provided with a $\frac{5}{8}$ bolt



II.—Portion of Stack, 6Feet Diameter, 100 Feet Long.

to fasten to the sheet being hoisted. If $\frac{5}{8}$ rivets are being used this bolt should be a $\frac{1}{2}$-inch bolt so as to go in and out of the rivet holes easily.



Mast is 13'-0" long to handle 4'-0" or 5'-0" sheets
Flexible steel cable
13' Round
Bar Iron
Sheave Wheel
Crane chain
Wood stop just clears sheave to keep cable in place
This size for 5'-0" stacks Varies with size of stack

Fig. 1—Detail of Crane for Erecting Steel Stacks.

The suspension cage shown in detail in Figure 2 is substantially constructed of pine, the two uprights and support for flooring being of $3\frac{1}{2}$ by $3\frac{1}{2}$ stuff. The flooring is composed of 2-inch planks and the railing of $1\frac{3}{4}$ by $2\frac{3}{4}$ stuff. The supports for the flooring are tenoned through the uprights and fastened with bolts. There are also two tension supports of $\frac{3}{4}$-inch round iron which are bolted through the floor to the floor supports. At the top of the uprights are two grooved wheels which are hung by bar iron supports twisted in such a manner that the wheels will run on the circumference of the stack. At the bottom these uprights have fastened to them two small crown faced wheels which prevent the cage from coming into contact with the stack.

The winch may be of any convenient size or description to suit the erector so long as it is powerful enough to lift the heaviest sheet. It is placed preferably in line with the soot door through which the cable comes from the crane.

The forge should not be too large as it is used inside the stack on the same platform where there are two men wielding their rivetting hammers, consequently there is but little room to spare.

Method of Erection.

The manner of erection is as follows: It is supposed in the following that the brick foundation of the stack has already been completed and is now ready for the cast iron stack base which is fastened to the brickwork by heavy anchor bolts of suitable length and strength. The scaffolding is built up inside the brickwork to within about twelve inches of the top and then the platform is laid loose upon it. The platform (see Figure III) is made of 2 by 4-inch stuff, there being six uprights with two 2 by 4-inch pieces laid flat across the top. The two outside couples of uprights are connected by two pieces also 2 by 4-inch. These pieces should be about 10 inches from the circumference of the stack at their centres and extend on either side to the circumference. About 3 feet 5 or 6 inches below the platform the support for the crane is laid across two tie pieces placed on the uprights for this purpose. The crane mast is stepped through the platform with its heel through this support. The cable runs through the platform, passing over a sheave wheel placed opposite the soot door and thence through the door to the winch.

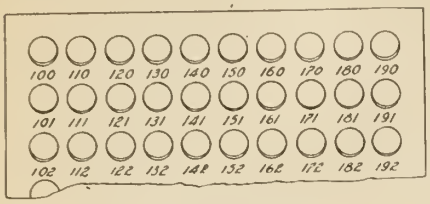
Machine Shop Costs

By G. C. Keith.

THE TIMEKEEPER.

(*Continued from January.*)

IN the time office the first duty of the timekeeper is to note and register the time each workman enters and leaves the shop. In many Canadian shops the opening hour is seven o'clock



FORM OF BOARD

Fig. 1.

and the closing hour six o'clock, making ten hours a day's work. A very good and simple system of registering the working time of an employe is the check system. Many clock systems have been devised, but in these a mistake is much more easily made than in either of the following systems. Where the shop is divided up and there are several exits the cabinet may be employed to advantage. Each employe is given a check bearing a number, which number is used for his name during his stay with the firm. A man enters in the morning, takes his check from the hook on a board under which is a number corresponding to the number on the check, and drops it in a box beneath the cabinet. In this cabinet are also hooks with numbers corresponding to the checks. When the whistle blows at seven or one o'clock the timekeeper removes the checks still remaining on the board and hangs the checks in the box on the hooks in the cabinet and he keeps track of the absent ones. The door of the cabinet is then closed. In this age of electricity it is an easy matter to arrange a catch so that when the timekeeper touches a button in his office the

Fig. 2.

latch is lifted and the door thrown open by spring hinges. At twelve and six o'clock the workmen remove their checks from the cabinet and hang them on the board. They are then ready for the workmen when they return at one or seven o'clock. The cabinet is then closed so that the men have access to it only when the whistle blows at twelve or six o'clock. Cabinets for this purpose can be bought from manufacturers who make a specialty of cost supplies.

Another efficient method and one which may be employed in the smallest shops is the check system with the use of the boards only. Boards one inch in thickness and two feet long by eighteen inches wide are prepared in the following manner: Holes of $1\frac{1}{2}$-inch diameter are bored to the depth of $\frac{1}{8}$-inch. Leave about $\frac{1}{4}$-inch between the holes at the side and $\frac{3}{4}$-inch between the top of and the bottom of the next. At the bottom of the hole a slight cutting is taken out by means of a chisel. This allows the

check to be easily removed. Numbers are printed beneath the holes and the checks, made a little smaller than the holes and of brass bearing corresponding numbers, are inserted in the holes above their numbers. These check boards when not in use may be arranged in a cabinet. Before starting time the timekeeper arranges them on a long table in front of his wicket. If it is a small shop an ordinary table will serve the purpose. As the workmen enter in the morning or at noon each man is given a number which is his during his stay with the firm. When the man goes out again at twelve or six he drops his check into a box prepared for the purpose. This box has a hole in the top just large enough to admit one check. This system has one disadvantage. The workmen carry around their checks all day and are liable to lose them. Before twelve and six o'clock the board is "called off" by the timekeeper's assistant and the numbers of the men absent are noted. If a workman leaves before twelve or six he must produce an order from the foreman. The timekeeper then takes the check and marks down the hour of his departure. The following day a form is filled out with the num-

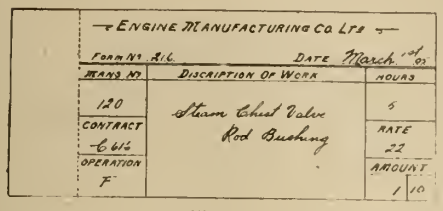
mium men hand in a statement of their work to the timekeeper. A form such as the one shown in No. 4 of Canadian Machinery may be used.

Another form that may be used and will explain itself is the following :

The following instructions are printed on the back :



ENGINE MANUFACTURING Co Ltd

FORM No. A16. DATE March 1st 05

MANS. No	DISCRIPTION OF WORK	HOURS
120	Steam Chest Valve Rod Bushing	5
CONTRACT 612		RATE 22
OPERATION F		AMOUNT 1 10

Fig. 7.

"This card is to be signed by the foreman on completion of job.

"Operator to give completed card to timekeeper.

"On starting a new job foreman will fill out a new card containing a description with pattern number for the operator.

"Timekeeper on his daily round will record on this card the time spent each day.

"A separate card to be used for each job."

It entails very little additional outlay in obtaining an account of the work done by the other men in the machine shop. This should be obtained before closing time. If a man goes out early have him give an account of his work and for the others the timekeeper can go around the machine shop and obtain from each man a list of his work for the day. Supposing our machine shop to be building engines. Then for each operation and contract a leaf like the following would be filled out :

DAILY DISTRIBUTION OF WORK

612		613		614		615		616	
1	15	1	14		67	2	25		
1	16		67		68	2	25		
1	10	1	10	1	10	2	00		
1	10	2	10	2	00	2	25		

Fig. 8.

The total amounts on each slip are added together and correspond with the total amount of the shop statement. These are then sent to the office of the cost clerk, who uses them to obtain the detailed cost of the engines. One entry is made on each slip, which is about 3x6 inches or any convenient size. The timekeeper must write out the operations of the premium worker on these slips also before attempting to make a balance. In the place for operation, (F) is put for fitting, (Pl) for planing, (D) for drilling, (T) for turning, etc.

Before sending these to the cost department it is the duty of the timekeeper to make out a form showing the daily distribution of work.

The cost of repairing, watching, etc., is charged to M.S. (machine shop), and is added to the cost of the contracts in proportion to the other labor costs.

This is also sent to the cost clerk for reference and it may be arranged afterwards showing the totals.

Fig. 9.

The per cent. charge is calculated on the productive labor and covers taxes and other expenses. It is an average per cent. taken for a number of years. This per cent. is also added in obtaining the true cost of a machine.

The timekeeper each fortnight or semi-monthly or monthly, according as the men are paid, fills out a payroll which is sent up to the cashier's office.

This payroll is for use where a premium system is in use. For a piece-work system a little different arrangement would be necessary. The day-work hours would go in the column for hours. Where the column "total hours" is there would be two columns, "hours piece-work" and "total hours," and under "premium" would be "piece-work."

PERSONAL MENTION.

Mr. W. T. Standish, manufacturers' agent, of Toronto, has become special representative of Brown-Boggs Company, Limited, Hamilton, Ont., with a view to further extending the sale of the numerous lines manufactured by this firm.

Mr. T. T. Simpson, civil engineer, Ottawa, has been appointed engineer for the town of Parry Sound. Plans are now being prepared for a new electric and hydraulic plant, and contracts for the water wheels will be closed in a few weeks.

Mr. G. F. Spry, for six years foreman of the boiler department of the Polson Iron Works, has gone to Collingwood to a similar position with the Collingwood Shipbuilding Company. Before leaving he was presented with a traveling case and a gold headed umbrella by the men in his department.

Mr. R. J. Young who has been a conspicuous figure in the life of the Canadian Manufacturers' Association during the past four years, as secretary of the organization, has resigned to accept another position. Mr. Young is now salesmanager of the Canadian Rubber Co., of Montreal, in which position he will doubtless meet with unqualified success.

Mr. R. O. McCulloch, of Goldie & McCulloch Co., Galt, met with an unfortunate accident while driving near his home town. The horse shied, overturning the vehicle and throwing Mr. McCulloch to the ground breaking his right arm at the elbow and shaking him up generally. Mr. McCulloch's friends will be glad to know that he is recovering rapidly.

A prominent Canadian in the person of Mr. Chas. F. Gildersleeve passed away at his home in Kingston, on Jan. 18. Mr. Gildersleeve was of the sixth generation of that name to engage in the shipbuilding and steamboat business, being prominently known as manager of the R. & O. Navigation Co. He was founder and first president of the Canadian Marine Association. He was a public spirited citizen, and took an active interest in the country's welfare.

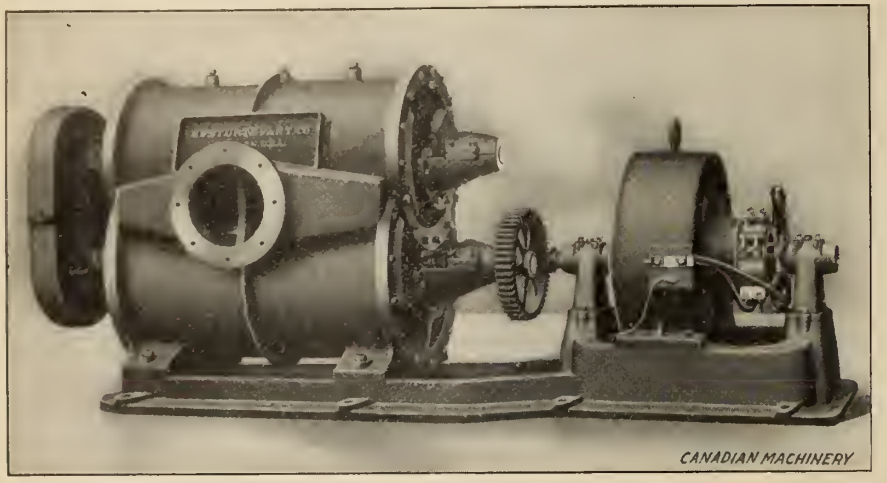
Mr. Genzo Kobayashi, representing the Japanese Government, is in Canada this month studying the systems adopted by the Canadian Pacific and Grand Trunk Railways. He thinks the Manchurian Railway can be run much along the same lines as the Canadian roads. Mr. Kobayashi is a typical Japanese, is well read, and has traveled extensively. He has studied the railroads of other countries as well, with a view to reporting as to the best plan to adopt in his native country.

Power and Transmission

Steam Gas Electricity Compressed Air Water

CONSTRUCTION OF NEW HIGH PRESSURE BLOWER.

HIGH pressure blowers are now made by B. F. Sturtevant in two types ; in the horizontal, the two shafts lie in a horizontal plane, while in the vertical one shaft is above the other. The blower consists of a cast-iron shell or housing in which are two rotating members or "rotors." One of these, the impeller, revolves in the larger portion of the casing which in the vertical type is the lower. It does the real work of compression. The other rotor, known as the idler, does no work ; it successively provides spaces or chambers of proper shape at the desired points in the revolution.



General View of Sturtevant Blower, Motor Connected.

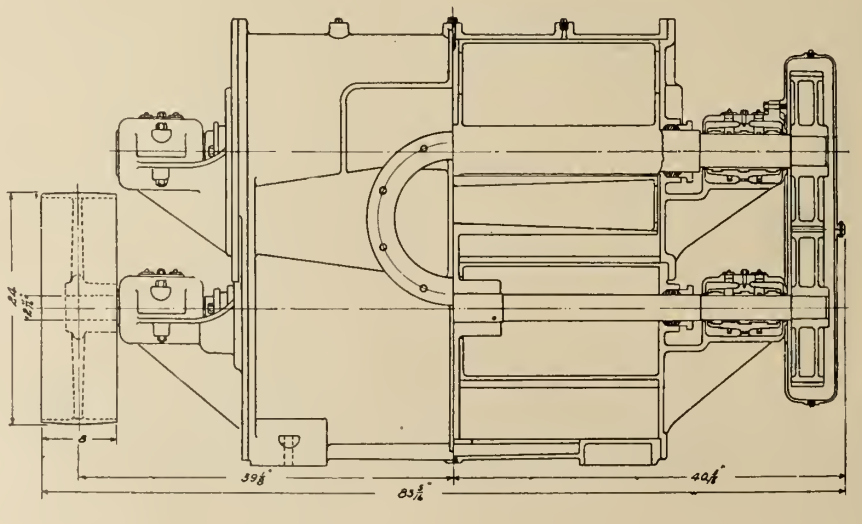
Ample clearance between the rotating members and the casing insures high mechanical efficiency by absolutely preventing internal friction due to contact of metal surfaces. Between the idler and the impeller the space is so great that only excessive variation in the accurate running of the gears will allow the two rotors to come in contact. This clearance is at least $\frac{1}{8}$-inch in small blowers and in large sizes $\frac{1}{2}$ to $\frac{3}{4}$-inch.

The idler, or drum, revolving in the smaller part of the casing, which in the vertical type is above the impeller, is symmetrical and has a periphery nearly a complete circle. It consists of three hollow vanes or blades cast in one piece with the shaft, which is of cast iron, very rigid, and of ample strength to transmit the little power necessary for rotation. The idler, revolving with large clearance, is turned at the same speed as the impeller by means of two spur gears running in oil.

The impeller, mounted on the driving shaft, is made up of three diamond-shaped bars or blades and a central web which is keyed to the steel shaft. Being symmetrical it is perfectly balanced at all speeds. As it revolves three separate pockets are formed in the annular space between the shell and a core extended lengthwise of the lower part of the casing. In reality the core is in two parts, each cast in one piece with the end plates, the space between them allowing the web to revolve.

The cast-iron shell or casing consisting of two hollow cylinders partially intersecting, is accurately bored and amply strong and rigid to withstand the strains due to handling, setting on foundation, and operation at high pressure. The ends of the casing are finished to receive the four cover plates in which are cast chambers or passages for lessening the noise and increasing the efficiency of the machine, as is explained under "Operation." On either side of the housing are openings for the intake and the discharge of the air, flanged and tapped for standard gas pipe fittings ; the small sizes have openings at the sides, and the large blowers openings at the top and bottom. In every respect the casing and rotors are symmetrical, permitting the blower to run in either direction.

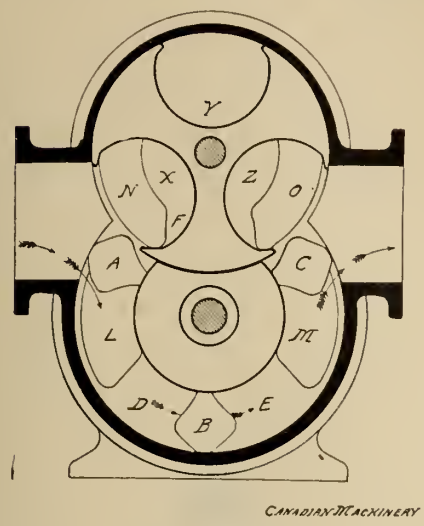
Except in blowers of large size, the lower half of each journal box is cast in one piece with the cover plate, insuring rigidity, simplicity and correct alignment. The boxes, except those for very small blowers, are of the ring-oiling type, lined with Sturtevant white metal, hammered in, and accurately bored.



Side View—Sturtevant High Pressure Blower.

When it is desired to maintain absolutely constant pressure the blower is provided with a relief valve, or auto-

matic governor. For transferring gases and air at high pressure, stuffing boxes are provided for the shafts, and a drain



I

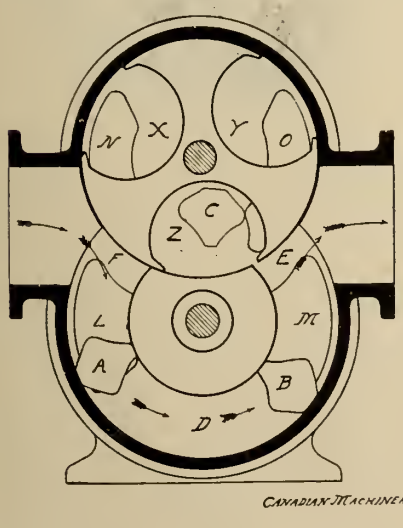
Position One—High Pressure Blower.

in the bottom removes tar and other distilled liquids.

Operation.

Air at atmosphere pressure entering the blower at the intake is successively imprisoned in the three pockets formed by the three blades of the revolving impeller, and discharged at any desired pressure up to ten pounds per square inch. The volume of free air delivered varies directly with the number of revolutions ; the pressure varies with the resistance met in the delivery pipes.

The principle upon which the blower operates is clearly shown by the accompanying diagrams, which are sectional views of the rotors and casing. In the



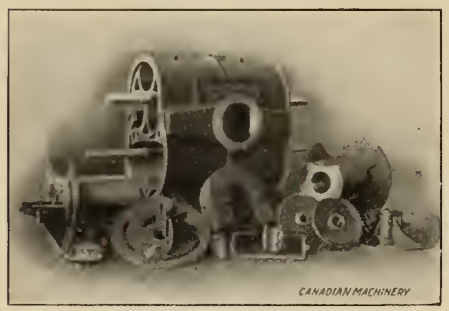
II

Position Two—High Pressure Blower.

explanation it is assumed that the blower is running at a speed to produce average pressure, and that this pressure exists in the discharge outlet.

While the rotating members were in the positions shown in Figure 1, air entered freely and completely filled the chambers (X) and (D), while pockets (E) and (Z) were discharging air to the delivery pipe. From the previous movement of the rotors, the pressure in (Y), filled with air carried over by the revolving idler, had been increased slightly by air flowing through the leakage passage (W) as will be explained later. The space between blades (A) and (C), just above the concave portion of the core, was practically filled by the wing of the idler, and consequently while in this position it took no part in the action.

While revolving from the position of Figure 1 to that shown in Figure 2, the air in pocket (D) has been carried along, and the communication between chamber (D) and the inlet has been cut off. Space (Z) is filled with compressed air, which further movement will carry toward the suction end where it will flow back to the inlet and in escaping cause noise. But this noise and loss is prevented by the leakage chamber (O) which allows the pressure to be transmitted to the air



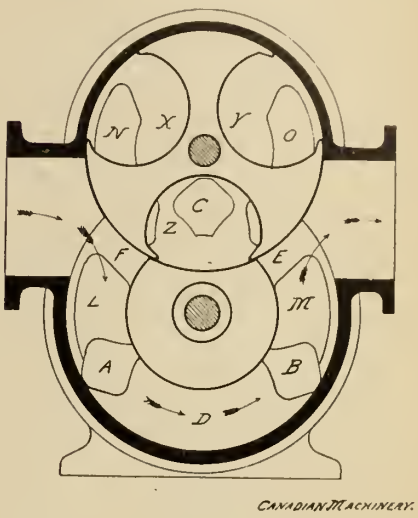
Parts of High Pressure Blower.

in space (Y), thereby increasing its density just before it is discharged.

Continued rotation carries the rotors to the position shown in Figure 3. Atmospheric air is now entering pocket (F), the air in (D) is being carried around between the blades (A) and (B) in the annular space, and (E) is discharging. Above the impeller the remaining pressure in (Z) is being transmitted to the air in (X) by means of the leakage passage (E) provided for the purpose, thereby making its pressure a little greater than atmospheric. The air in space (Y) under slight pressure from previous leakage is imprisoned and being carried around by the idler.

When the fourth position is reached, pocket (F) will be filling, the pressure in chamber (Z) will have been reduced to atmospheric by leakage, space (Y) will discharge and a little compressed air from the delivery pipe will flow back through leakage passage (M) and increase the pressure in (D), which will result in a quieter discharge when further movement brings (B) into the discharge passage.

The purpose and advantage of the leakage chambers is now apparent ; they make it possible to recover the pressure

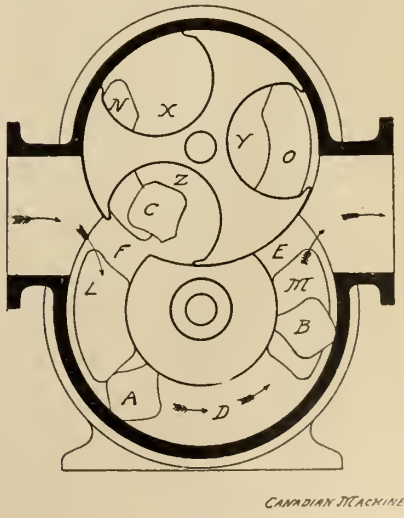


III

Position Three—High Pressure Blower.

tending to escape from the impeller pockets and by making the increase in pressure gradual, cause the blower to run with less noise. Leakage passage (L) has little effect when the blower runs in the direction shown here ; it is made to allow the blower to be reversible.

It will be noticed that the impeller carries three blades, set at equal distances around the periphery, thus causing three admissions of air at each revolution. Upon leaving the position shown in Figure 4 the rotors quickly reach a position in which the conditions are exactly the same as those shown in the



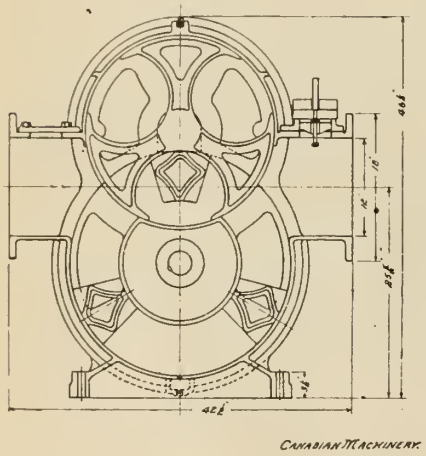
IV

Position Four—High Pressure Blower.

first figure, the operation continuing as explained.

In selecting a blower for the foundry it is customary to rate the volume of

air according to the maximum amount of iron which the cupola can melt. The capacity of the cupola being known, the size of the blower may be found from the fourth column of the accompanying table. If the maximum output is not known the diameter of the cupola becomes the basis for computation, the first column of the table giving the usual capacities for the diameters given in the second column. The values in the third column are based on 30,000 cubic feet of air per ton of iron ; our tests show this to be a fair average, although 23,000 to 40,000 cubic feet may be required, depending upon the local conditions and method of operation. In case a given cupola requires less than 30,000 cubic feet per ton, the blower will melt a larger amount of iron than that given in the table.



End View—High Pressure Blower.

WESTINGHOUSE THREE-CYLINDER COMPOUND AIR PUMP.

By F. H. Parke.

ONE of the latest designs in air pumps is found in the Westinghouse compound air pump, consisting of three cylinders placed vertically in tandem. The two lower ones, joined by a thin centre piece, constitute the air end of the pump, which is surmounted by a centre piece and steam cylinder of the regular Westinghouse type, so that in general appearance this new pump, although somewhat longer, is very similar to that which has been identified with the air brake system throughout the country ever since its inception. The design is very compact and, since the air end only is compound, the additional features required are so similar to old standards that the same simplicity of operation is assured.

This pump can hardly be said to be new, since the Westinghouse Brake Co., in London, have built similar pumps for some years, and have them in successful operation both in England and on the continent of Europe. Therefore, the placing of it on the American market is not in the nature of an experiment as far as the design and operation of the pump are concerned. The application of them to American railway practice is, however, new, and several of the railroads have already placed them in service on trial.

Need of Such.

The greatly increased weight of cars demanding larger brake cylinders, coupled with the increased length of trains, has brought about the expenditure of a much greater quantity of air, and, naturally, the requirement of a larger air pump. This fact brought out the 11 in. pump. With the introduction and general adoption of the high-speed brake and high-pressure control apparatus, the main reservoir pressure was raised from 90 lbs. to 130 lbs. Consequently the work of the pump was thereby greatly increased, and its consumption of steam found to be a factor of considerable importance. The introduction of an air pump designed to deliver the increased amount of air, and at the same time require less steam, has been made a necessity which both the railroads and the air brake companies have for some time past recognized. Such a pump must combine the requirements just outlined with the same simplicity of operation and maintenance, as well as the absolute reliability now had in the standard pumps. Such a pump this three-cylinder Westinghouse compound pump is designed to be.

Compounding.

Generally speaking, the compounding of the air end is done as follows : The two air cylinders are of the same diameter, each having a piston suitably connected to the piston rod, which is actuated by the steam piston. A cast iron cylindrical drum of smaller external diameter than the inside diameter of the air cylinders, projects from one air piston, connecting it with the other in such a manner that the two pistons and drum form a sort of spool. The centre piece between the air cylinders fits

Fig. 1—Front View.

closely about the spool, and has packing rings to prevent the passage of air from one cylinder to the other past the surface of the drum. The low-pressure air is drawn into the top of the upper cylinder and the bottom of the lower cylinder, and during compression is forced through suitable valves and passages to the annular volume formed between the spool, air cylinder walls, and centre piece. The final compression takes place in this annular volume, and the air is forced out through the passages and valves in the centre piece to the discharging opening. It will thus be observed that in each air cylinder both high and low pressures are single acting, but that these pressures on the air piston as a whole are double acting.

The resultant effect, therefore, on the steam piston rod is almost the same as in the simple pump, but the air-cylinder surface being twice as great as in the simple pump affords greater opportunity for radiation of heat, and for that reason the temperature of air discharged is very satisfactory for locomotive service.

Also by thus compounding the air end, a much smaller steam cylinder can be used to operate the pump, causing a marked economy in steam consumption.

General Design.

The present design of pump consists of a steam cylinder 8 in. in diameter by 12 in. stroke, and two air cylinders 11 in. in diameter by 12 in. stroke, while the small outside diameter of the spool is 8¾ in. Consequently the capacity is similar to that of the standard 11 in. pump, which has been on the market for some years, having air and steam cylinders each 11 in. in diameter by 12 in. stroke. The compound pump has an 8 in. diameter steam cylinder instead of an 11 in., as with the standard, and the steam consumption is thereby reduced to about 52 per cent. of the latter through this change alone. But by compounding the air end the capacity of the pump is increased about 16 per cent. when pumping against 90 pounds air pressure, due to the fact that the low pressure clearance volumes at the end of a compression stroke are filled with air at 40 pounds or less, instead of 90 pounds, as in the simple pump, and in the former case this pressure reduces to the atmospheric pressure much earlier during the intake stroke than is possible with the standard pump, consequently the volume of air drawn in at each stroke is that much greater. For higher air pressures this saving is greater.

The air valves, valve seats and valve cages are of the same pattern as those used in the 11 in. pump, while the steam valve mechanism corresponds exactly with that of the 9½ in. pump. Also the piston rings of the two air pistons are similar to the 11 in. pump, and the steam piston rings correspond to the standard 8 in. pump, many of which are still operating on railroads. The steam and air connections, also, are made up of standard pieces that are now in use on the other pumps, so that by the introduction of this new compound the amount of repair stock required outside of that already needed by railroad shops is very small.

Since the working parts are all modelled after those of existing standard, the knowledge possessed by repairmen at the present time will serve them in their work on the new pump without any extended extra instruction. The rules already issued for operating air pumps will in nearly all cases apply to the new pump, so that its introduction, in almost every way, will cause no trouble or inconvenience to the operating departments.

Illustrations.

The cuts illustrating this article will give a clear idea of the design and operation of the pump for those who are interested sufficiently to follow it through. Figure 1 is a front view of the pump, showing the general arrangement. It will be noted that the steam cylinder is made both right and left hand, so that the steam and exhaust connections can be made on either side,

Fig. 2—Side View.

or both on either one side. The lower thin centre piece connecting the two air cylinders contains the final discharge valves and orifice. Each air cylinder has a suction strainer through which the air is drawn into its low pressure volume.

Figure 2 shows a side view of the pump, indicating more clearly the position of the air valves and ports, as well as the lugs for supporting the pump in position.

Figure 3 shows a front central section of the pump, and a side view partly in outline and partly in section. From this cut the operation of the pump can easily be followed through. Steam enters from the governor at the steam inlet and passes through the port (a,) (a,) to the cavity (B) over the main valve; from thence it goes to either the top or the bottom of the steam cylinder exactly as in the present 9½ in. or 11 in. pumps. It is hardly necessary, therefore, to follow this part of the operation through in detail, as that of the standard Westinghouse pumps is not new.

Operation.

The operation of the air end, however, will be of interest. On the down stroke air is drawn in through the upper air inlet on the left hand side of the air cylinder; it passes through the passage (F) and receiving valve port (m) to the low pressure volume above the piston (11). When the piston reaches the lower limit of its stroke and starts upward, this air is compressed until the upper discharge valve (34)—on the upper right hand side of the cylinder—is raised, then the air is forced through port (r',) discharge valve (34,) passage (g',) receiving valve (34) and port (m2) to the annular cavity between the drum portion of piston (11) and the cylinder (5.) Since this volume is much smaller than the low pressure volume, the air is being compressed during its passage from the low to the high pressure volumes, until when the piston reaches the upper limit of its stroke, the air in the low-pressure clearance passage and high-pressure volume has reached the intermediate pressure of approximately 40 pounds.

During the following down stroke, this high-pressure air is compressed until it raises the final discharge valve (34,) when it passes through port (r2) and the discharge valve to the discharge orifice in the centre piece between the air cylinders.

This same operation occurs in the lower cylinder when the piston goes in the opposite direction from that described above, and as corresponding passages are designated by the same letter, the operation can be readily followed through by reading over the description just given.

The air cylinders are lubricated by the automatic air-cylinder oil-cup, (48,) shown in Figure 3, which affords a constant lubrication of an amount automatically regulated to the work done by the pump.

Thus the complication due to compounding is, by this design, materially reduced; all parts are made strong and durable, and as nearly like standard simple pumps as it is possible to make them. In this way the great reliability that has been so prominent a feature of the Westinghouse pumps is made to apply to this one also.

NEW POWER HOUSE.

THE new power house of the Electric Light Company, at Glace Bay, N.S., is being installed with its complement of machinery. The power house has just been completed, being 75 x 42 feet, the contract price of which was $8,000. A retaining wall of solid concrete was built, and inside this wall a steel concrete smokestack 105 feet in height. The power house is divided into two compartments, the boiler room and the engine and condenser room, with a neat little office in the latter. A representative of the Robb Engineering Co., Amherst, N.S., is now engaged in setting up and installing a 375 h.p. Robb-Armstrong, horizontal, tandem compound, Corliss engine, arranged for a direct connection with a 250 k.w. generator, and a 150 h.p. Robb-Mumford boiler, with a steel case. A representative of the Canadian General Electric Company is also engaged in installing machinery supplied by that company. This new machinery, which is up-to-date in every respect, consists of an alternating current revolving field generator, a 12 k.w. exciter mounting an engine shaft operated at a speed of 150 revolutions per minute, and a beautiful blue Vermont marble panel switchboard. This machinery will be supplemented by a large engine and dynamo, and the switchboard now in use, and two of the boilers used in the old building have been moved to the new boiler room. The system now supplies 6,000 lights.

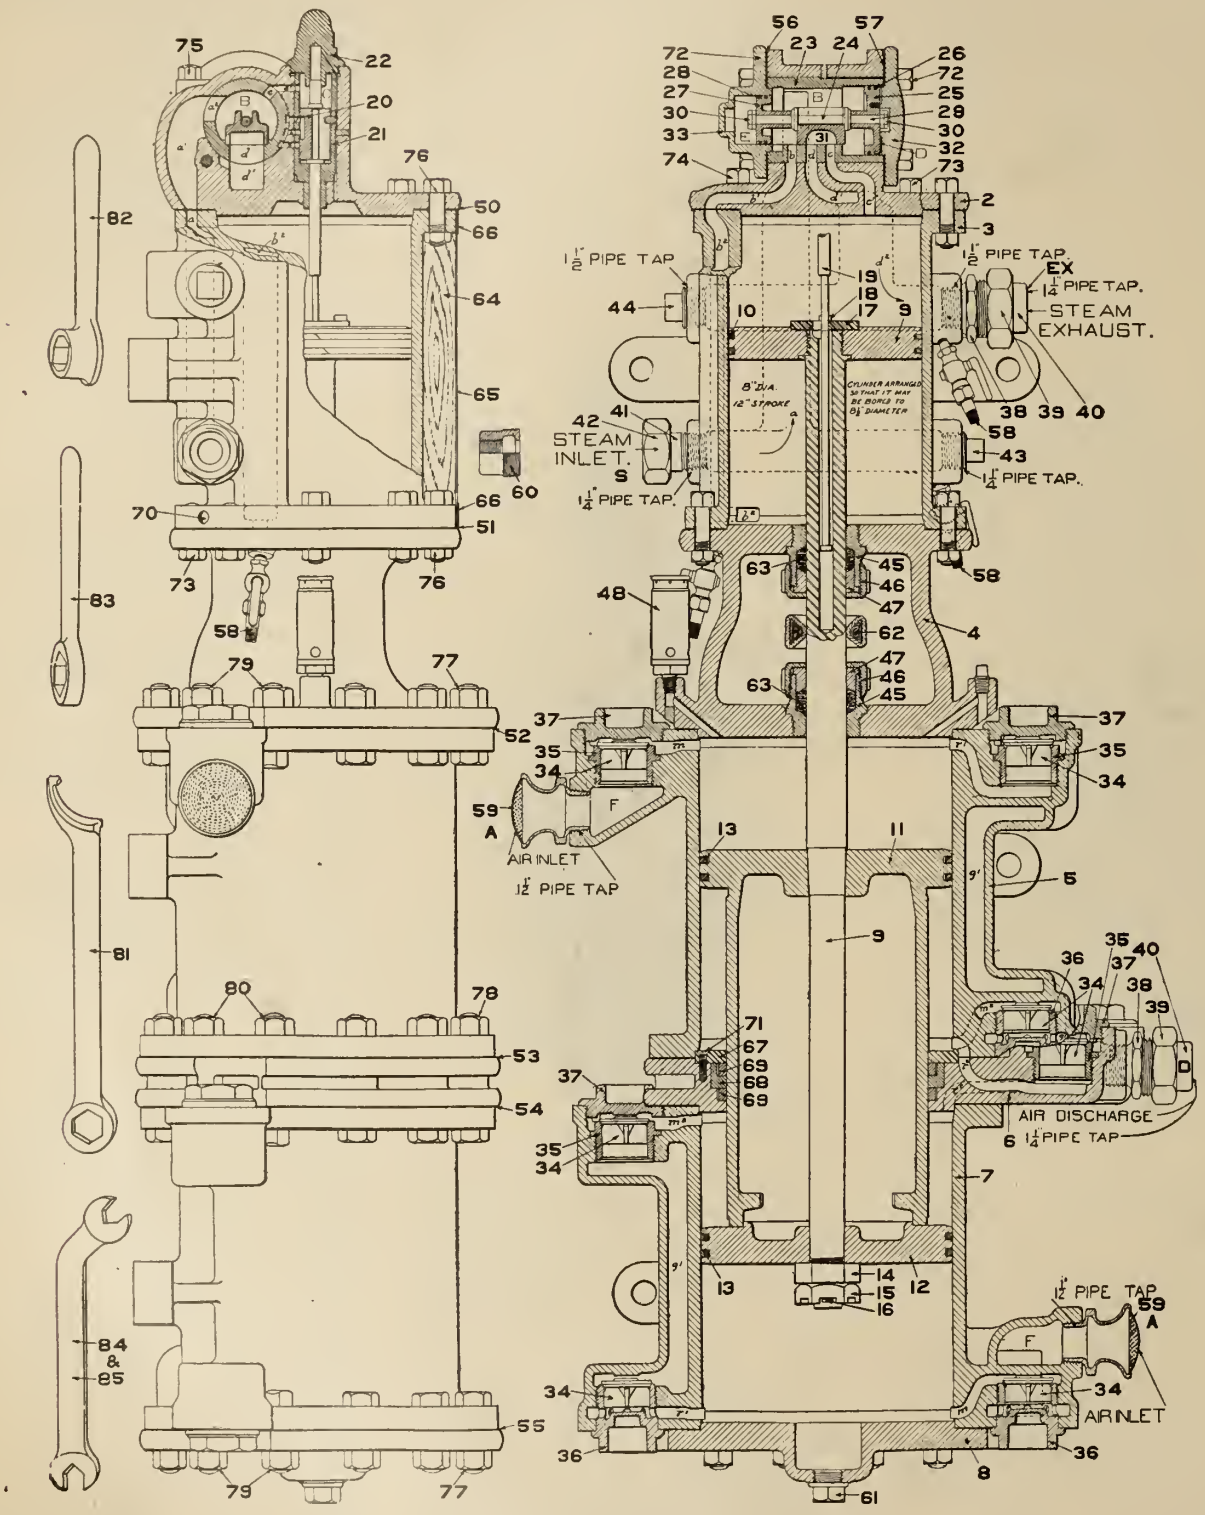

Fig. 3—Detail of Westinghouse Air Pump.

ABOUT CATALOGUES

By mentioning Canadian Machinery to show that you are in the trade, a copy of any of these catalogues will be sent by the firm whose address is given.

Westinghouse Blotters. The Westinghouse Co. are sending out attractive calendar blotters, illustrating their different lines of electric fans.

Green Mattawan is the title of a small booklet just issued by the Green Fuel Economizer Co., Mattawan, illustrating their steel plate blowers and fans. Size, 3 1-2 x 6 inches.

Radial Drills. The Bickford Drill & Tool Co., Cincinnati, Ohio, are sending out bulletins of their 2 1-2, 3 and 3 1-2 foot radial drills which contain complete information concerning these high grade tools.

Gas Boosters. The latest of the engineering series issued by B. F. Sturtevant Co., Hyde Park, describes the safety gas exhausters as boosters, and their application in manufacturing plants. Size, 6 1-2 x 9 inches.

Electric Hoisting Machinery. Bulletin No. 62, issued by the Crocker-Wheeler Co., Ampere, N. J., deals with the adaptability of the electric motor to hoisting apparatus, giving good illustrations and a short description of same. Size, 7 1-2 x 10 inches.

Electro-Dynamic Co. Two bulletins, one describing the motor drive as carried out with the inter-pole variable speed motor of this firm, and in the other some attention is paid to the motor itself. In the latter the method of obtaining sparkless commutation is dealt with.

Canadian Fairbanks Calendar. The Canadian Fairbanks Co. have issued a large calendar suitable for shop or office, which should be an acquisition to any firm. They stated that they would be pleased to furnish this to any of the readers of Canadian Machinery, so same may be had by addressing a card to the above company.

Francis Reed Co. have sent their illustrated catalogue and price list, showing to advantage the different styles of upright drills made by them. These include a wide range up to multiple spindle drills. Their upright nut tapper is also dealt with, as well as drill chucks. Size, 6 x 9 inches.

National Machinery Co., Tiffin, Ohio. Bulletins illustrating the National hot forge and nut machines, and the National hot pressed nut machines, have been received. These lines of machinery have been greatly improved recently and are meeting with signal success on the American and Canadian market.

Crocker-Wheeler Calendar. A calendar for the first three months of the year is being distributed by the Crocker-Wheeler Co., Ampere, N.J. On this is illustrated the 4,000 k.w. alternating current generator manufactured by this firm. Canadian agents are the Packard Electric Co., St. Catharines, Ont.

Twentieth Century Machine Tools. This catalogue, issued by B. F. Barnes Co., Rockford, Ill., contains 74 pages. The main part of the catalogue is devoted to the different lines of drills manufactured by this company, including single spindle and gang drills of all sizes, screw cutting lathes, while punches and chucks are given some attention.

Time Recorder. The new improved premier Canadian time recorder, and the Canadian Magneto watchman's time detector, are described in a fourteen-page catalogue issued by the Canadian Time Recording Co., Toronto. The method of operation is illustrated, and the advantages of this system over many others is dealt with. Size, 6 x 9 inches.

Westinghouse Circuit Breakers. The latest bulletin issued by the publicity department of this firm refers to the Westinghouse Automatic Circuit Breakers, carbon break. These are illustrated and the different points of design explained. Tables are given of sizes, and capacities of different styles. A small folder, with an artistic cover, treats of the Westinghouse pipe thawing apparatus.

Small Tools. A 200-page catalogue of Pratt & Whitney Co., New York, contains perfectly illustrated views of the different small tools manufactured by this company, including amongst others, milling cutters, dies, single and in sets, reamers, threading tools, knurling tools, gauges and many other special lines. At the back of this book are given tables of relative English and metric equivalents, also standard sizes of threading pipe drills, etc. 4 3-4 x 7 1-4 inches.

Pumps. A number of bulletins describing the many lines of pumps manufactured by the Smart-Turner Machine Co., Hamilton, gives some idea of the wide scope of manufacture capable of being produced at this company's works. They include standard duplex boiler feed, automatic feed pumps, centrifugal pumps, independent jet condensing apparatus, compound duplex steam pumps, sewage pumps, single vacuum pumps and many others. These are in bulletin form. Size, 6 x 9 inches.

Industrial Progress. A 300-page pamphlet issued by the Massachusetts Bureau of Statistics of Labor gives an idea of the opportunities for industries that have not yet been utilized in Massachusetts, being part 4 of the annual report for 1905. This gives the different towns and cities in the state, the population, railway connection, and other advantages, besides considerable general information as to the future outlook. Such a publication should have a good effect from an educational standpoint. Size, 5 3-4 x 9 1-4 inches.

Ivel Agricultural Motor. In an interesting series of illustrated folders, the motors manufactured by the Ivel Agricultural Motors, Limited, London, England, are described. To read this and see the wide possibilities of the gasoline or petrol motor in farming, one would think that instead of being one of the most strenuous farming must, with these methods, be indeed a pleasure. Illustrations are given showing ploughing, reaping, harrowing and threshing by machinery. This line of machinery should have a wide field in this country.

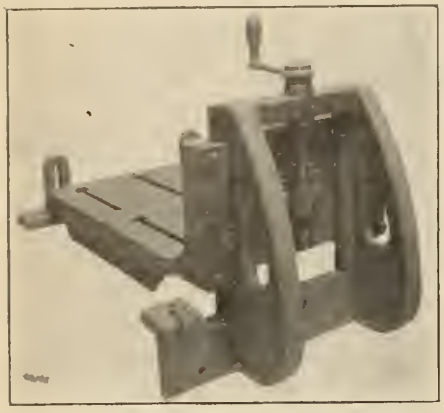
Pedlar People. This is the heading on an unusually attractive and well designed catalogue issued from the head office of the Pedlar People, Oshawa, Canada. It contains an insert showing portraits of the heads of this firm. Throughout is illustrated the many attractive designs of ceiling and wall ornamentation effects manufactured by them. Some of these are particularly artistic, especially the frieze panels. Anyone at all interested in this line of work should have this catalogue. A similar one dealing with accessories and outdoor designs has also been issued and is of equal importance with the other.

Machinery Development

Metal Working **Special Apparatus** **Wood Working**

LATHE ATTACHMENT FOR BORING

SUCH an attachment is for converting a lathe to a horizontal boring mill, and is designed to equal the output of a mill both in quality and quantity within its range, and can be

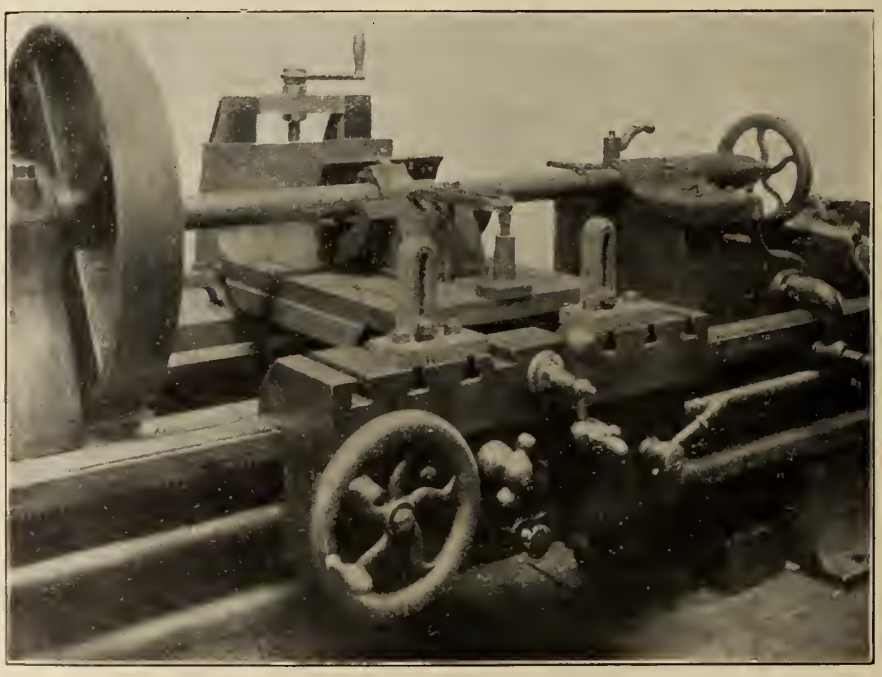


Underwood Drilling Attachment.

made for any size lathe. It consists of a lower plate with an angle projecting down and fastened to the back side of the carriage. The surface of this angle plate is planed true with all the other parts of the attachment. The fastening device has a true planed and well fitted slide with an adjusting screw for elevating to bed for holding the work. For a 30-inch lathe the bed has three T slots for $\frac{5}{8}$ or $\frac{3}{4}$-inch bolts, is 31 inches long, $22\frac{1}{2}$ inches wide, and has $5\frac{1}{2}$-inch vertical adjustment. When set on the lathe carriage it is true with the carriage in all directions—on the upward projection it is planed true, so that work can be set quickly and a place to measure from and set in line with the lathe spindle. By the vertical adjusting screw the table is either raised or lowered parallel with the lathe shears. After being brought into position, the two slotted angle pieces (these having been previously bolted on front of carriage) are firmly attached to table by two screws shown, holding the bed to the lathe carriage. It can readily be seen that it gives a true adjustable bed equal to any well designed machine tool for holding pieces to be bored. No blocking up is required or other slow methods so common when using a lathe for this kind of boring. With this device it takes a very short time to make the change for boring — remove the tool slide, and drill and tap two holes in the back of carriage, lift the device on, and in a very short time it is ready for the work. In practice a 3-inch or $3\frac{1}{4}$-inch diameter bar with suitable cutterheads and automatic feed is desirable, attaching one end of the bar to face plate of lathe, the other end in steady rest or other bearing, and we at once have a powerful boring mill, and do not depend on the lathe centres, which would be the weakest part of this kind of boring. This makes a handy and useful attachment for any shop, weight for 30-inch lathe 685 pounds, of which all sizes are manufactured by H. B. Underwood & Co., 1025 Hamilton street, Philadelphia, Pa.

RAILROAD AND MANUFACTURING SHAPER.

IN the illustration of a 32-inch railroad and manufacturing shaper, is shown the latest product of the Cincinnati Shaper Co., Cincinnati, Ohio. It has been designed to have great power, and at the same time given sufficient rigidity to withstand the peculiar and excessive strain to which it is subjected. The column is of unusual width and depth, is ribbed and braced internally, and of a form to resist to the highest degree the peculiar strains to which it is subjected, and the horns projecting at the front and back give an unusually long bearing to the ram. The ram has a wide and long bearing in the column and is of a form which practice has proven to be the best. The rail is deep, heavy, ribbed horizontally and strongly gibbed to the column, and the cross traverse screw is provided with a graduated collar reading to .001 of an inch, and is also provided with their variable automatic feed, which is changeable from nothing to full feed while the machine is running. There are felt wipers between the column and the rail. The head swivels to any angle and is graduated; the locking device is simple and highly efficient, and the down feed screw is provided with a graduated collar, reading to .001 of an inch. The journal of the main gear has two diameters, (i.e.) the inner end is twice the diameter of the outer; overcoming any tendency to break at the junction of the gear, and there is a third or outer bearing to the cone shaft. The crank block is a steel casting and is set well into the cup of



Multiple Drilling Attachment in Operation.

the gear, permitting the rocker arm to travel close to the edge of the gear; thus avoiding the usual overhang.

There are full-length taper gibs throughtout, adjustable endwise by single screws; namely, for the ram, head, rail, apron and crank wheel slides; affording metal contact on both sides of the gib. This, while more expensive to make, is decidedly preferable to gibs with set screws impinging with varying pressures at the several points in the length of the gib. This machine may be used either in single or back geared form, the ratio of gearing being in the one case seven and two-tenths of the cone shaft to one stroke of the ram, and in the other thirty to one; the highest ratio of any machine of its stroke made. The cross feed connecting rod is automatically adjustable to any height of the rail, and is not dependent upon frictional contact. An outer support, as shown, is regularly furnished with each machine, without extra charge. This, to be of any practical use, demands two conditions, one a base stiff enough to withstand the thrust put upon it, the other that the surface the support rolls or slides on shall be truly parallel with the travel of the table. These conditions are met with in this shaper. Ball bearings are provided under the elevating screw to the rail, and the screw, of telescopic form, never receding below the floor, is out of the way of falling chips. The vise is of their improved double screw form, has a graduated swivelling base, and permits straight or tapering pieces to be securely clamped with equal facility and with rapidity. Its jaw plates are of annealed tool steel.

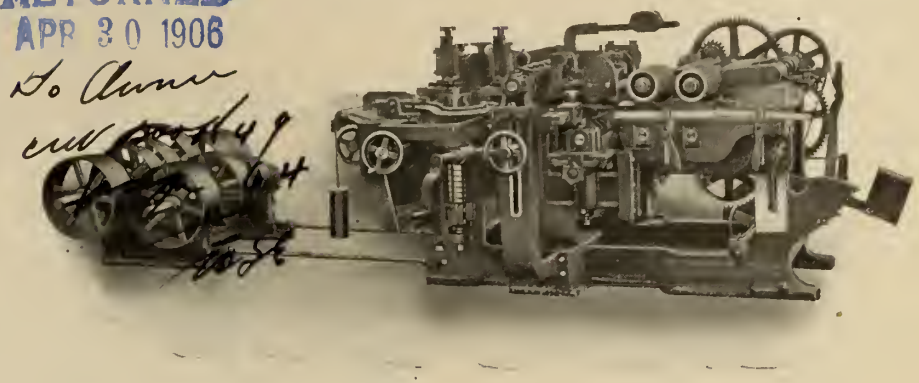
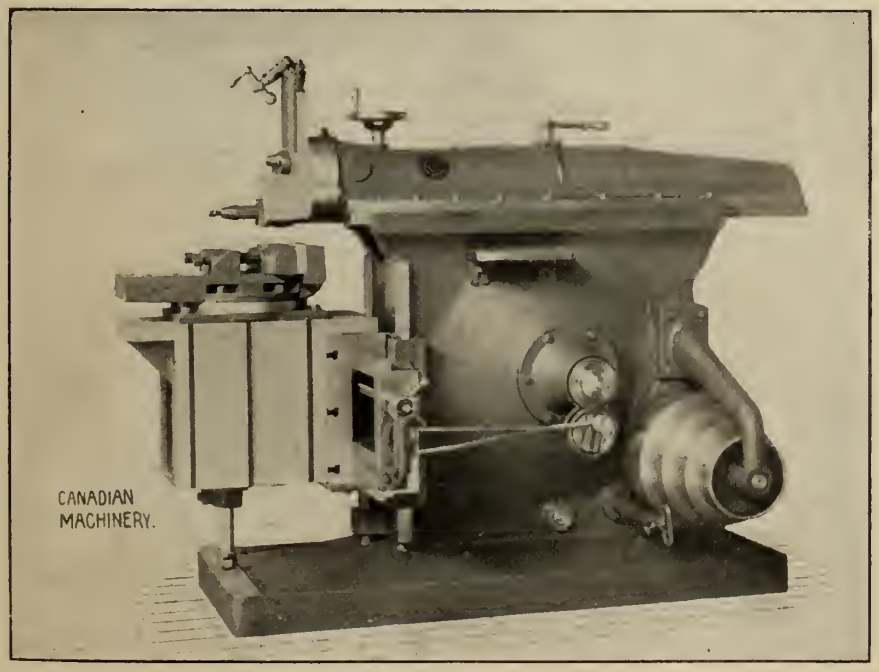
APR 30 1906



New MacGregor-Gourlay Molder.

Key-seating of shafting and of similar work up to four inches in diameter, is provided for by an opening through the column under the ram. All material entering into the construction of the machine is of the highest class. All shafts are of high point carbon steel, and all are accurately ground in our own shop, and all shaft bearings are long and well braced in the column. All gears and tee slots are cut from the solid; all bearings are amply large, and all flat sliding surfaces, as well as the surfaces between the apron and the table, are hand scraped to surface plates.



Cincinnati Heavy Shaper.

All pinions are of cast steel, and all bevel gears are cut from the solid bar. The rocker arm is strong and heavy. Means are provided for compensating for wear. Convenient means are provided for lubrication, an important consideration. The length of stroke is changed from the working side of the machine, and its position by means of a hand wheel on top of the ram, and these changes can be made while the machine is in motion or at rest.

MacGREGOR-GOURLAY MOLDER.

THE molding machine shown in the following illustration built by the MacGregor-Gourlay Co., Galt, Ont., possesses some new and interesting features. The chief characteristics of the machine are the placing of the countershaft at the rear end, the lower head cutting first, and the variable feed. With these superior advantages it will do more and better work than the old style.

The frame being detached from the countershaft is so designed that all parts dependent upon it are well supported and strongly braced, and metal distributed in a manner to obtain the best results.. The advantages gained in detached countershaft are convenience to operator, more power obtained from belts which deliver straight from side head pulleys, and ample room for belts, avoiding contact with frame or use of idlers.

The lower head cutting first gives the stock a finished surface to rest upon table while the other heads are operating upon it. The table in front of head is independently adjustable to regulate depth of cut, and yoke in which it is contained can be drawn out for adjusting and setting knives.

The pressure shoe and bars which are necessary in connection with cutter heads above the table have vertical and longitudinal adjustments and are arranged to swing entirely clear of heads to give access for adjusting and sharpening knives. The pressure shoe for side head in table is weighted, and adjustable to and from knife. The entire table with all its attachments is raised and lowered by screw and crank. Ball bear-

ings are introduced to take thrust and carry weight, making the adjustment easy for operator. Tightening bolts and nuts are provided with hand wheels or levers, which saves time in completing adjustments.

The variable feed is one of the most important features of this machine, and is described in article on molder design in January issue. A variation from to 60 feet per minute can be obtained by simply moving a lever.

The mechanism is of ample strength to withstand hard and continuous service, and can be relied upon to feed against any depth or width of cut.

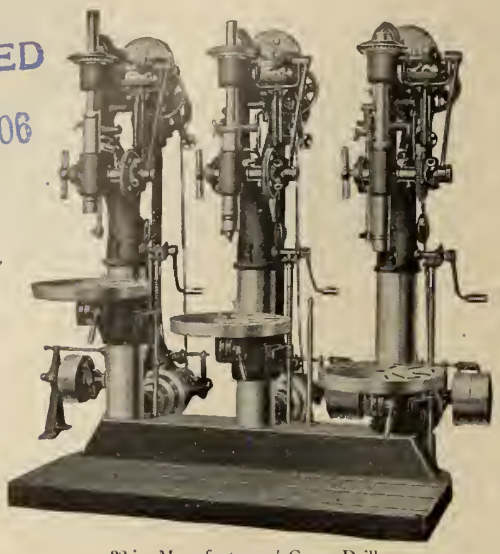
The gearing in connection with this feed is powerful, and so arranged that upper rolls are driven downward upon stock. The design and the high standard of work entering into the construction of this machine puts it in the forefront of modern molders.

RETURNED
APR 30 1906

MANUFACTURERS' GANG DRILL.

GANG drills of various capacities are manufactured by B. F. Barnes Co., Rockford, Ill., the latest of which, a 23-inch manufacturers' gang drill with self-operating spindles, independent table style, is shown herewith.

The spindles in this style are set on a heavy bed base and are provided with back brace, making an exceedingly rigid, strong and powerful machine for its size, and is furnished with or without back gearing as desired. The spindles are self-acting, requiring only the throwing of the trip lever, when the spindle immediately descends very rapidly to the work at which point the feed is automatically thrown in and the spindle begins to drill at regular speed ; as soon as the automatic stop trips, the spindle rapidly returns to original position



32-in. Manufacturers' Gang Drill.

ready for the next operation. There are no feed levers to bother with, hence the operator has practically all of his time for taking the work to and from the machine. Each spindle has independent feed and independent speed. The individual column style provides for independent, adjustable tables for variation in heights of work. The tables are regularly furnished in round style, but when oil pump attachment is required, square tables are supplied with oil channel, the extra charge being made only for the oil pump attachment. The machine can be used for boring and reaming work equally well. It is especially adapted for the use of high speed steel on work requiring durability under constant use. It will regularly handle work up to a 2-inch cored hole, but where required for still heavier work, extra heavy crown gear and pinion is furnished which gives capacity up to 3-inch cored work.

HEAVY WOODWORKING MACHINES.

AS examples of heavy woodworking machines, two manufactured by the Berlin Machine Works, Beloit, Wis., are shown in the accompanying illustrations, Fig. 1 representing the Invincible sander, and Fig. 2 representing a planer, matcher and sizer. In reference to the latter, an important feature of this tool is the location of the lower cutter head, which cuts first. This not only produces much better results in working thin stock, but, in running timbers, it tends to straighten the crooked pieces, which in other machines would be difficult to feed. The lower in-feeding rolls and bar before the lower cylinder are adjusted by means of a lever at the in-feeding end for changing the cut of the lower cylinder from

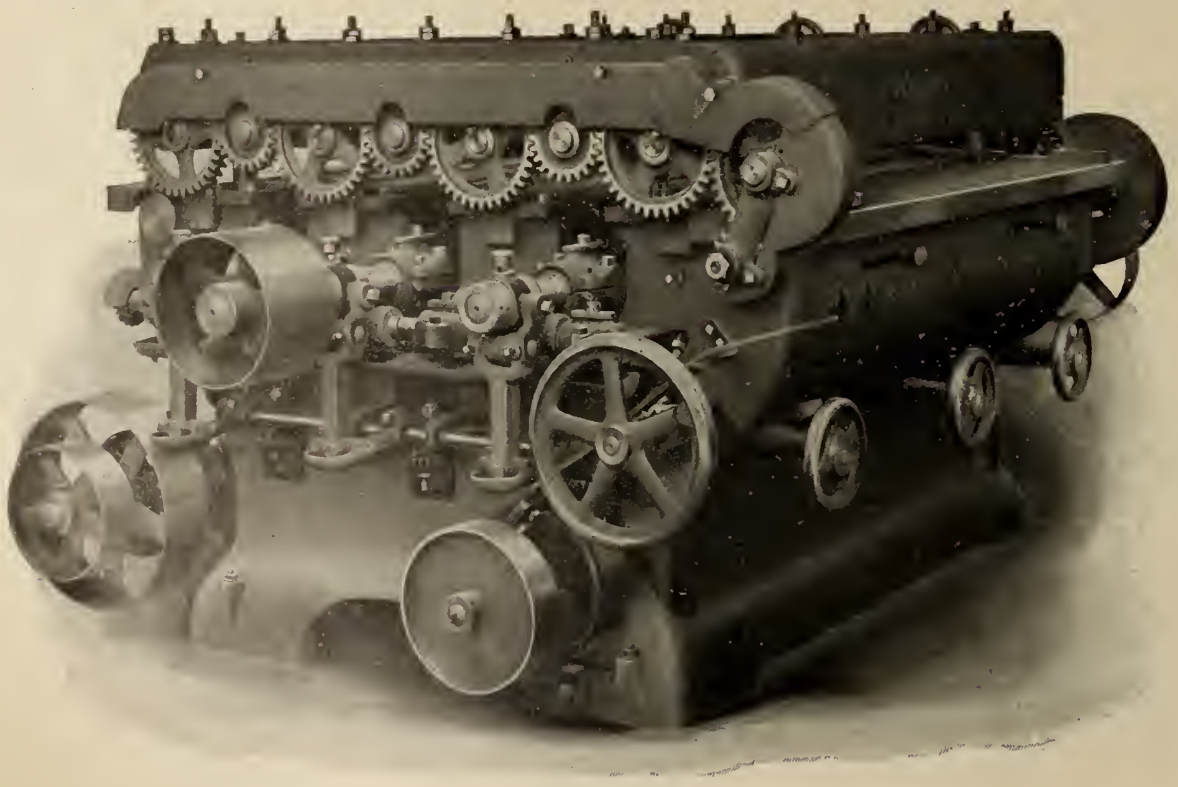


Fig. 1—Invincible Sander.

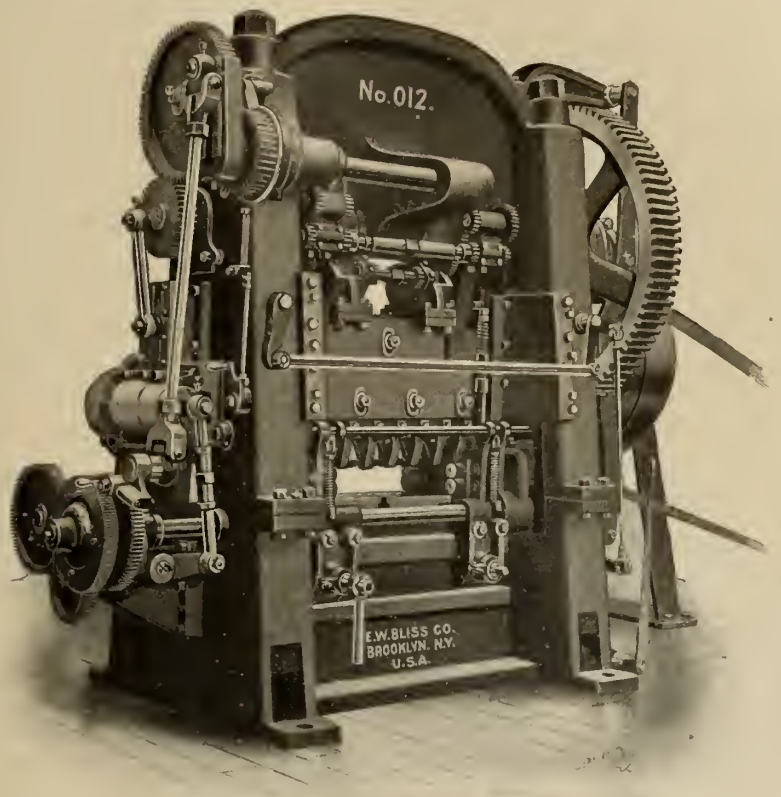
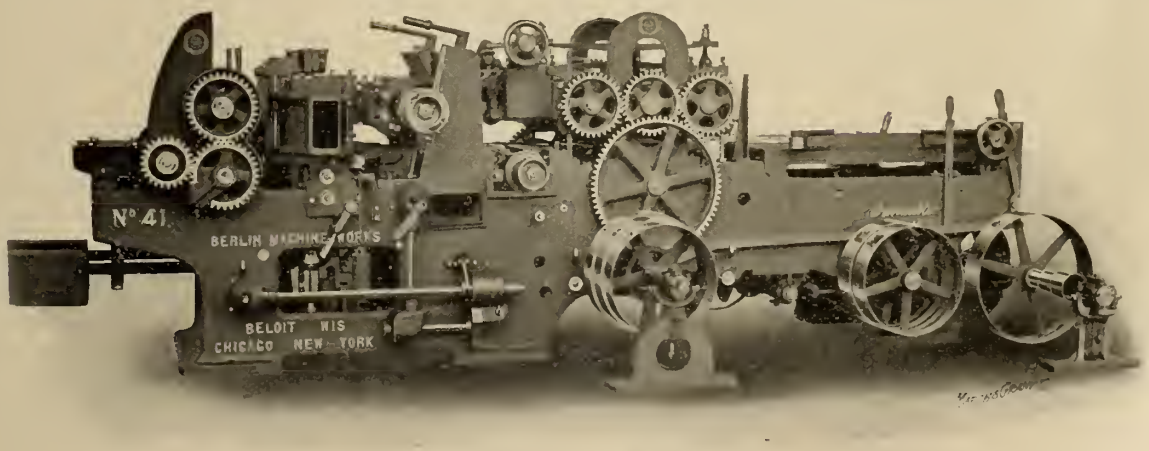
0 to 1-4 inch. The under head is arranged to draw out at the side of the machine for convenience in sharpening and setting of knives. The top rolls, upper cylinder, pressure bar and chip breaker are adjusted simultaneously, or the in-feeding rolls independently by power. Like results are obtained by hand when desired. No gears run on studs. All cutter heads are square and slotted, four sided. Top and bottom heads, each double belted. All cylinder pulleys are pneumatic.



Multiple Punch Press.

The sander is built in sizes from 30 inches to 102 inches in width. Three drums are used, carrying different grades of paper—coarse, medium and fine. Following the drums is a brush cylinder, which serves to keep the last lower feed roll clean, thus preventing marring of the finished stock by dust particles, which otherwise would collect upon the roll. All drums have an oscillating motion which removes scratches caused by imperfections in the paper. Each drum may be independently adjusted at either end, and, to determine the cut, may be simultaneously adjusted and locked at both ends by means of a hand wheel at the in-feeding end. Eight powerfully driven feed rolls are used—four above and four below—and each may be independently adjusted and securely locked at each end. The upper frame carrying the feed and pressure rolls may be quickly adjusted by power and accurately set by a partial turn of a hand wheel convenient to the operator. The feed may be instantly started or stopped by shifting either of the buttons shown just below the in-feeding table, or by a lever at the rear of the machine, either of these buttons or the lever operating a clutch on the feed shaft. The drum is the most important part of a sander, and it is this feature of the Royal which has put it in a class by itself. The drum is so constructed and the paper so applied to it, that it is continuous cutting. It leaves no marks like the ordinary drum, having a longitudinal opening through which the edges of the paper must pass for clamping.



Invincible Planer, Matcher and Sizer.

A NEW BLISS MULTIPLE PUNCH PRESS.

HEREWITH is shown a new multiple punching press especially designed by the E. W. Bliss Co., Brooklyn, N. Y., for operating narrow dies of great length. Although the holes punched by the press are usually not large, the number of them produces an enormous strain, and, therefore, a heavy press is required. It is particularly adapted for gang punching work, such as plates for boilers and tanks, or other large sheet metal articles and tools, and perforated sheets requiring a large number of perforations.

The press is fitted with a cam actuated stripper, which permits of much shorter, and, therefore, more durable punches than can be employed with stationary strippers. This stripper comes down upon the metal, straightening it out before and holding it straight during the punching and stripping. After stripping it moves up with the punches. This arrangement presents the additional advantage of obviating the blow

against the lower side of the stripper plate, which, with stationary strippers, occurs upon the return stroke of the slide, because of the necessary play between the die and the fixed stripper, which permits the punched bar or sheet to be carried up against the plate before stripping.

Another notable feature of this press is that it is fitted with open feed rolls, adjustable to take any size of sheet up to 50 inches wide. The feed rolls are provided with a side motion which automatically shifts the sheets and rolls sideways at each stroke for the purpose of permitting the perforating of a staggering pattern by means of a single row

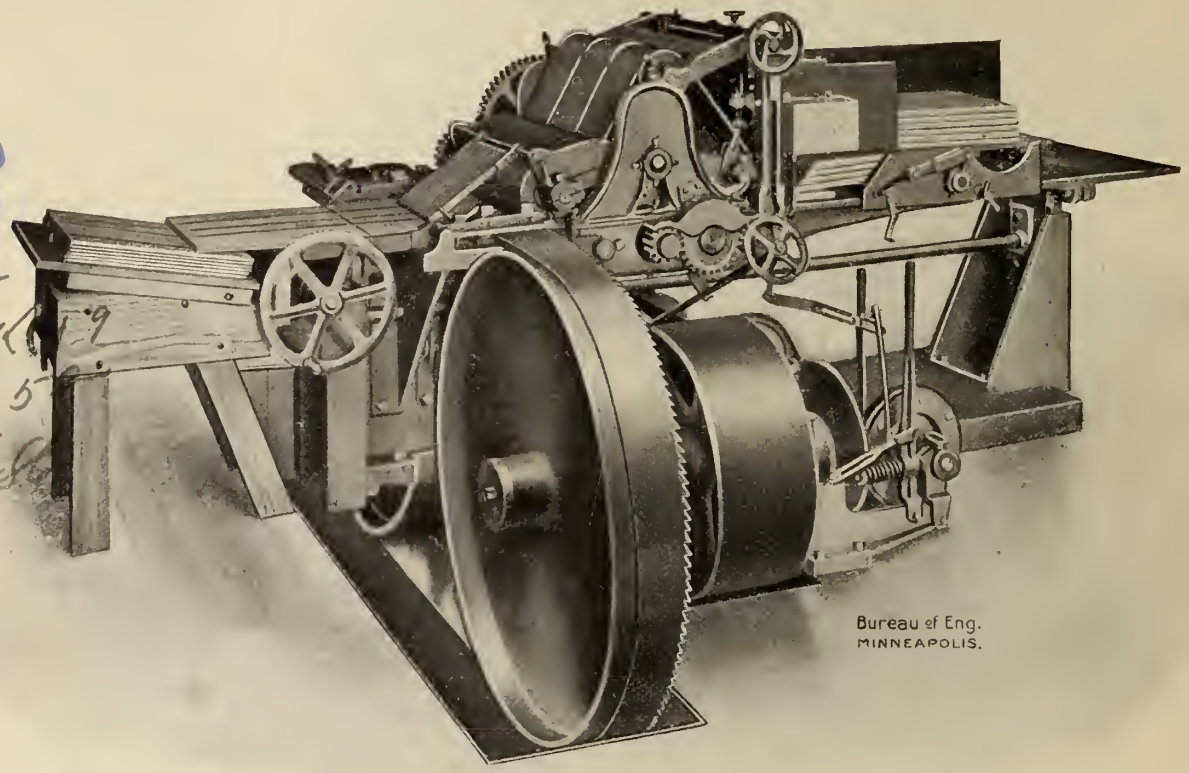
MINNEAPOLIS.



Cowan Boxing Machine.

die. This reciprocating motion, which shifts the rolls, can be easily adjusted for different patterns. A great advantage accruing from the use of a single row die, that will be readily appreciated, is that the intermediate holes in the dies being omitted, the remaining ones may be fitted with steel bushings set in a machine steel holder, avoiding the difficulties of satisfactorily hardening multiple dies made entirely of tool steel, and permitting of quickly repairing the damage done to any one of the dies by putting in a new bushing. In addition to this staggering motion the rolls have a variable feed motion quite original in design. This mechanism enables the rolls to feed an equal distance for two or three strokes, then varies the length of feed before making the next stroke. For instance, in a period of three strokes of the punch slide, the rolls may be fed two short and one long distance, or vice versa, or all three spacings may be equal. By substituting other ratchets and gears, a number of combinations may be obtained, thus securing a considerable variety of spacing or grouping of the row of holes.

The frame is built up in sections held together with four steel rods 4 1-2 inches in diameter, which materially strengthen the frame and take the strain when the press is in operation. The crank shaft is a solid steel forging 7 1-2 inches in diameter. The main gear, clutch, balance wheel, tight and loose pulleys are all on left hand side of press, supported by an out-board bearing. This arrangement leaves both the front and back of press free from all mechanism which might in any way interfere with the operator. The clutch mechanism is of the jaw type, and is actuated by an air cylinder. Alongside of the fly-wheel, which is 50 inches in diameter and 10 inches wide, is another wheel of the same dimensions, drilled with 12 socket holes, equally divided around the circumference, to receive starting levers for turning the machine over when setting the dies.

BRITISH POWER HAMMERS.

A NEW power hammer has just been placed on the market by Peter Pilkington, Limited, 75a Queen Victoria street, London, that is altogether different from former makes. This firm are pioneers in the matter of air compressor hammers, having furnished them to the English and foreign governments and to most of the leading shipbuilders and engineering firms in Great Britain.

The great advantage of this new hammer, which has compound cylinders and is worked from a separate air compressor, lies in the fact that where firms have a number of hammers and are dispensing with steam this hammer can be substituted and an air compressor electrically or otherwise driven to take the place of steam boilers. These hammers are remarkable for their very great economy as the high pressure air which has made the blow of the hammer is stored and used over again for lifting the piston and for light work. This firm are prepared to guarantee a saving of 50 to 60 per cent. in power as compared with steam, and in many cases will undertake to convert existing steam hammers by taking off the steam cylinders and replacing them with the company's patent compressor cylinder. An order for no less than 24 of these hammers has just been filled for a large shipbuilding works near Glasgow, with other orders pending from the same firm. It is intended in a subsequent issue to give a more detailed account of these hammers.

Companies Incorporated

Warden King & Son, Montreal, have been authorized to carry on business in the Province of Ontario in pipes, steam fittings, plumbers' supplies, etc., with a capital of $40,000.

The Colonial Cordage Company, chartered by the Dominion Government, has been licensed to do business in the Province of Ontario, with W. B. Converse, of Toronto, as attorney.

Elevator Specialty Company, Toronto, share capital $40,000, purpose to manufacture elevators and machinery. The directors are: G. A. Matthews, W. J. Feeney and G. Ritchie, all of Toronto.

Silver Bar Mining Co., Ottawa, share capital five hundred thousand, purpose to mine and mill minerals. The directors are W. D. Gregory, H. F. Gooderham, H. N. Barry, R. Weir and J. F. Boland.

The Lake Superior Corporation, a company incorporated in the State of New Jersey, has been given the right to carry on business in Ontario, provided they do not use a larger capital than $1,000,000.

Mac Mining Company, Toronto, share capital three hundred and fifty thousand, purpose to develop mining property. The directors are D. A. McPherson, Toronto, Geo. Chapman and W. E. Buckingham, of Guelph.

Siche Gas Co., Toronto, share capital $100,000; purpose, to manufacture, sell and operate gas apparatus and supplies. The directors are F. L. H. Sims, J. H. Chewett, and R. G. Hunter, all of Toronto.

Thorold Natural Gas Co., Toronto, share capital $40,000; purpose, to refine petroleum oil, natural gas, manufactured gas, or electricity. The directors are C. A. Moss, W. Gilchrist, and J. A. Thompson, all of Toronto.

Canadian Lock Nut Company, Toronto, share capital $300,000, purpose to manufacture lock nuts, bolts and machine fittings of all kinds. The directors are: A. G. Slaght, T. L. Monahan and E. C. Spereman, all of Toronto.

Fletcher Manufacturing Company, Toronto, share capital $250,000, purpose to manufacture bakers' tools, soda fountains, hardware, glassware, woodenware, etc. The directors are: B. Fletcher, E. Whaley and E. B. Fletcher, all of Toronto.

The Dominion Steel Car Co., Montreal, share capital five hundred thousand, purpose to manufacture railroad rolling stock. The directors are E. F. Surveyor, A. C. Casgrain, C. M. Cotton, J. W. Weldon and S. J. Lehuray, all of Montreal.

Vermillion River Iron Ore Co., Toronto, share capital $80,000; purpose, to carry on the operations of a mining, milling, reduction and development company. The directors are F. J. Denton, J. W. McDonald and Ella A. Francis, all of Toronto.

C. Parsons & Son, Toronto, share capital $150,000; purpose, to carry on the business of tanners, dealers in hides, leather, etc. The directors are C. Parsons, W. G. Parsons, Frances S. Parsons, Alice E. Parsons, and J. E. Boswell, all of Toronto.

C. Tompkins, of New York; Hon. H. W. Ladd, Boston, Mass.; W. Tompkins, Tompkins' Cove, N.Y., and C. J. Osman, of Hillsboro, N.B., have given notice of applying for incorporation as the New Brunswick Gypsum Company, Limited, with a capital of $30,000.

The Edmonton Lumber Co., capitalized at $60,000, has been organized, and a logging camp has been established eighty miles above Edmonton, on the Saskatchewan River, where a large mill will be erected. A. H. Clark, Edmonton, is promoter of the enterprise.

New York & Canadian Mining Co., Toronto, have been incorporated with a share capital of $40,000, for the purpose of carrying on the business of a mining, milling and reduction company. The directors are G. R. Geary, F. D. Byers, and O. F. Taylor, all of Toronto.

The Pittsburg-Cobalt Co., Toronto, share capital $75,000; purpose, to carry on the operations of a mining, milling, reduction and development company. The directors are C. D. Robbins, S. F. Heckert, W. A. McCutcheon, H. O. Patch and S. M. McElroy, all of Pittsburgh, Penn.

St. Lawrence Pressed Brick & Terracotta Co., Montreal, share capital two hundred and ninety-nine thousand, purpose to manufacture brick, etc. The directors are A. W. Blouin, O. Frechette and A. Brunelle, all of Montreal, and R. Lefebvre and F. C. Larose, of LaPrairie, Que.

The Robert Gardner & Sons Company has been incorporated to carry on business such as the manufacture of machinery, etc. It is composed chiefly of Montreal capitalists, with a total capital stock of one hundred and forty-five thousand dollars, and its chief place of business will be Montreal.

Dymond Development Co., Ottawa, share capital $250,000; purpose, to carry on the business of a mining, milling, reduction and development company. The directors are C. W. F. Gorrell, A. T. Shillington, of Ottawa, and B. J. Arnold, W. L. Arnold, and R. G. Arnold, of Chicago, Ill.

Canadian Voting Machine Company, Niagara Falls, share capital $100,000, purpose to conduct a general foundry and machine business. The directors are: C. F. Roland and A. M. Ecclestone, St. Catharines; J. T. James and J. R. Mencke, Bridgeburg; and W. E. Curran, Buffalo, N.Y.

The Central Heat, Light & Power Company, Limited, has been incorporated, with a total capital stock of $500,000. with its chief place of business in Montreal, to carry on the business of a light, heat and power company in all its branches. The company is composed chiefly of Montreal capitalists.

The Ontario Cobalt Developing Co., Toronto, share capital $350,000; purpose, to carry on the operations of a mining, milling, reduction and development company. The directors are S. M. Hay, J. W. Curry and E. E. Wallace, of Toronto; J. Bingeman, of Berlin, and J. K. Paisley, of Ottawa.

Meakins Brush Co., Montreal, share capital sixty thousand dollars, purpose to take over the business of Meakins, Sons & Co., manufacturers of brushes, etc. The directors are C. W. Meakins and W. G. Meakins, Hamilton, Ont.; F. A. Ritchie, Toronto; C. W. Meakins, H. R. St. Michael, J. J. Robson and M. Thivierge, all of Montreal.

The Excelsion Babbit & Car Bearing Co. has been organized at Moncton, N.B., by Joseph R. Stratton, R. A. Borden, E. M. Jones, Jas. D. Ross, Moncton; and Edmund Simpson, Petitcodiac. The object is to manufacture and deal in babbit and other anti-friction metals, car bearings, etc. The capital stock is to be $190,000.

The Sudbury Machine Shop & Foundry Co. have been incorporated with a share capital of $40,000, for the purpose of carrying on the business of mechanical engineers, machinists and foundrymen, the provisional directors being D. H. Haight and John Lawson, Copper Cliff; A. B. Gordon and L. O'Connor, Sudbury, and O. R. Smith, Victoria Mines.

Campbell & Tough Stock Scale Co., Arnprior, have been incorporated with a share capital of $50,000, for the purpose of manufacturing and dealing in weighing machines, refrigerators, etc., and carrying on the business of woodworkers, machinists and founders. The directors are D. J. Campbell, Arnprior; R. J. Tough, Toronto, and D. Craig, Renfrew.

The Canadian Consolidated Mines, Toronto, have been incorporated by Dominion charter, with a capitalization of $5,500,000. The incorporaters include H. S. Osler, W. B. Raymond, E. Ford, J. M. Ewing, and Britton Osler, and the company is organized for the purpose of amalgamating several successful mines at Rossland with the Trail Smelter and the Rossland Power Company.

Dominion Brazing Co., Montreal, have been incorporated with a share capital of $100,000, for the purpose of carrying on a business of brazing, welding, soldering, repairing, etc., and to manufacture and deal in all goods used in connection therewith. The directors are A. Hendery and W. Eckenstein, of Montreal; H. L. Dinning, Lachine; C. Ralph, Longueuil, and C. A. Duclos, Westmount.

Two powerful contracting syndicates were incorporated last week, one to be known as the MacArthur Construction Co. of Canada, with a capital of six million dollars and headquarters at Montreal. The incorporators are Archibald and A. F. MacArthur, of Chicago; J. R. MacArthur, of New York, and W. J. Poupore, of Montreal. The other is to be known as the Empire Construction Co., headquarters in Montreal, and a capital of one million. The incorporators are J. B. Tudhope, of Orillia; H. W. Fleury, of Aurora; P. Galibert and T. Gauthier, of Montreal, and a number of distinguished Belgians.

INDUSTRIAL PROGRESS

MACHINERY AND MANUFACTURING NEWS would be pleased to receive from any authoritative source industrial news of any sort, the formation or incorporation of companies, establishment or enlargement of mills, factories or foundries, railway or mining news, etc. All such correspondence will be treated as confidential when desired.

A new electrical company is being promoted at St. John's, Nfld.

The Eagle Spinning Mills Company are to establish a large plant at Hamilton.

A large new saw mill is to be built at Beaudette, on the Rainy River, next Spring.

The London Machine Tool Co. will remove their plant to Hamilton in February.

The Sawyer-Massey Company, of Hamilton, are to erect a large warehouse at Saskatoon.

The Niagara Engine Works at Niagara-on-the-Lake, Ontario, has been put in operation.

R. P. Inglis, Montreal, is making preparations to establish a street railway at Edmonton.

Keenan Bros. will extend their woodenware factory at Owen Sound at a cost of $25,800.

A beet sugar plant is proposed at Chatham, Ont., to be financed by American capitalists.

The Backus-Brooks syndicate are to erect a lumber mill in the vicinity of Fort Frances, Ont.

The Terminal Warehouse and Cartage Co., Montreal, are to erect a $200,000 fireproof warehouse.

C. Lloyd & Sons, Wingham, are considering increasing their plant, installing new machinery, etc.

The Niagara Engine Works are to be put into operation shortly. Orders for 30 engines are on hand.

C. Anderson, St. Louis, and T. Morton, Chicago, may establish a smallwares factory at Sarnia.

Messrs. Knight & Stitt will erect a new flour mill at Eganville with a capacity of 100 barrels a day.

New coal fields at Beaver Lake, near Edmonton, are reported to be of a very high grade of bituminous coal.

A large brickmaking plant employing 150 men is to be established at Clayburn, near Mission City, B.C.

The International Silver Company, Welland, are installing considerable new machinery and electric equipment.

A hydraulic engineer is to investigate the subject of developing power at the Reversible Falls at St. John, N.B.

The Climax Road Machinery Co., composed of American capitalists, may establish a Canadian factory at Guelph.

Sheldon & Sheldon, Galt, Ont., are installing a dry kiln apparatus for the Improved Match Co., Drummondville, Que.

McInnes & Lyons have established a planing mill at Edmonton, in connection with their large saw mills near that city.

The B. C. Electric Railway Co. are to erect a power house at North Vancouver, for their new tram line at that place.

The Canadian Pacific are rapidly pushing ahead the work of double-tracking between Winnipeg and Fort William.

The Canadian Pacific Railway propose to construct a line of railway from Woodstock to Niagara Falls, through Hamilton.

Work on the big power plant at Fort Frances is progressing favorably, and it is announced that a pulp mill will be built there.

A shipment of 100 cars of steel rails has been made from the "Soo" to be used by the C.P.R. between Fort William and Winnipeg.

Sheldon & Sheldon, Galt, have just closed the contract for the heating, ventilating and drying apparatus for Stauntons, Limited, Toronto.

Sheldon & Sheldon, Galt, Ont., are installing drying apparatus for the Canada Glue Co., Brantford, and for the Canada Coating Mills, Georgetown.

The name of the Cobban Mfg. Co., Toronto, has been changed to the Phillips Mfg. Co. The personnel of the company remains unchanged.

The Fraser River Tanning Co., Limited, New Westminster, B.C., are installing a heating apparatus supplied by Sheldon & Sheldon, Galt, Ont.

The Miramichi Lumber Co. will establish a mill at Chatham, N.B. The plant and building will cost $50,000, and 60 men will be employed.

The Wellington Colliery Co., Victoria, B.C., are to commence boring operations on a new discovery of coal near Parksville, not far from Nanaimo.

The International Coal & Coke Co. are to install 100 new coke ovens. The increase in the daily production will be from 800 to 1,000 tons of coke.

Willis Chipman, Toronto, has prepared plans for the development of water power near Prince Albert, Sask., to supply that town with water.

The Quebec Central Railway intends to build several branch lines this year, and will enter Quebec City over the new bridge when it is completed.

The Credit Foncier Franco-Canadien has purchased a site in Winnipeg, with a frontage of 60 feet, and will build a large bank structure next Spring.

John Bertram & Sons, Dundas, have ordered from the Smart-Turner Machine Co., Hamilton, an automatic feed pump and receiver for their new factory.

Contracts have been signed and it is now assured that the Patent Roofing Company of Lafayette, Ind., will establish a branch factory at Brantford.

British Columbia shingles have been advanced to $1.85, an advance of 15 cents. It is said all grades of B.C. lumber are to be moved upward in price.

W. H. Northcote, Hamilton, has secured a permit to build a brick house in that city, to cost $1,800, and Mark Lawrence is to build one to cost $1,700.

James A. Ross, Wellandport, is promoting a company to operate an electric railway from Port Maitland, on Lake Erie, to Beamsville, on Lake Erie.

It is said that the Lake of the Woods Milling Co. propose duplicating their large mills at Keenwaning. Engineers are now at work on the surveying of a site.

Tenders have been asked for the construction of 450 miles of Grand Trunk Pacific from Touchwood Hills, 225 miles west of Portage La Prairie, to Edmonton.

An important pulp wood industry in which from $1,000,000 to $2,000,000 will be invested is to be established in the Back River district near St. Jerome, Que.

The Canadian Machine Telephone Co. has been granted a twenty-one year franchise by the city of Brantford. The price of the 'phones is to be $15 to $25.

L. O. Grothe & Co., cigar manufacturers, Montreal, have purchased a site for $32,500, and propose to erect factory buildings, etc., to cost about $200,000.

William Russell, representing the Independent Harvesters Company, of Chicago, has written Mayor Ferguson of Stratford in regard to locating a branch there.

Niagara Falls, Ontario, now has a factory in operation turning out machines for making concrete blocks. It is that of the Vining Brothers Manufacturing Company.

Sheldon & Sheldon, Galt, Ont., are installing leather drying apparatus for the Lang Tanning Co., Berlin, for the Acton Tanning Co., Acton, and for Beardmore & Co., Acton.

Legislation will be introduced at the coming session of the Ontario Legislature for the purpose of securing the refining in Ontario of all nickel produced in the province.

The Restigouche Woodworking Co. have completed the construction of a large woodworking plant at Dalhousie. The plant is said to be the most modern in New Brunswick.

The Canadian Tap & Die Company, who recently purchased the Clark & DeMill building at Galt, have received a consignment of thirteen machines, which are now being installed.

The Canadian Northern Railroad will spend $2,600,000; orders placed embracing 400 box, 400 flat, and 50 stock cars, 30 coaches, 16 baggage cars, 7 sleepers and diners, and 44 locomotives.

About one hundred men will move to Toronto from Stratford on account of the transfer of the factory of the Kemp Manure Spreading Machine Co. to Toronto by the Massey-Harris Co.

It is announced that the Canadian Northern Railroad will build a road to

skirt the north shore of Lake Superior, connecting their lines in Manitoba with their lines east of Georgian Bay.

The British Columbia Electric Railway Company have placed orders for electric machinery and equipment worth $125,000, to be used in enlargements of their power plant near Vancouver.

The N. B. Electrical Power Co., St. John, intend to establish a large electrical power plant at Aroostook Falls, and will have it in working shape before the Grand Falls plant is in operation.

Winnipeg financiers will establish an industry at Medicine Hat to be known as the Great West Sewer & Tile Company, with a capitalization of $1,000,000. Brick and tile will be manufactured.

The Lake Superior Box Company, West Superior, Michigan, have purchased a site in Winnipeg and intend to erect a five-storey factory building. Machinery to the value of $70,000 is to be installed.

The Klondyke Mines Railway is to be built from Dawson to Stewart Crossing, a distance of 84 miles. T. W. O'Brien has been in the east and has successfully arranged the financing of the project.

A company is being promoted to supply the town of Shelburne, N.S., with electric light and electric power. They will get their power from the Roseway River and expect to develop about 3,000 horse-power.

Manson Campbell, president of the Chatham Fanning Mill Co., has bought a site at Brandon, Man., for $10,000, and it is understood that the Chatham company proposes erecting a wholesale depot in Brandon.

The Wellington Colliery Co. has begun operations to open up a new coal field several miles from Wellington, where a splendid seam has been discovered. The firm of R. Dunsmuir & Sons control the Wellington colliery.

Amongst other new machinery installed by W. H. Banfield & Son, 120 Adelaide street west, Toronto, in their new plant is a 30x30-inch planer with an 8-foot bed, manufactured by John Bertram & Sons, Dundas.

Prescott expects to secure electric power this Spring from the Ogdensburg Light & Power Company, which secures its power at Hannawa Falls, and intends to look for business on the Canadian side this season.

An electrical expert has reported that there are from 12,000 to 13,000 horsepower to be generated, except in the dry season, at the power plant at Erindale, which was established with York County Loan Company money.

According to the report of the Ontario Bureau of Mines, the total mineral output in Ontario during 1905 amounted to $11,572,647. The report is in three parts, and can be obtained on application to the department.

There are now eighteen shipping mines producing zinc in British Columbia, the total production during 1905 amounting in value to $273,000. The operation of the smelting plant at Frank will give the industry a boom during 1906.

Three hundred tons of steel rails are being shipped to North Vancouver, where they will be used in the construction of a tram line through the townsite recently laid out across the inlet from the city of Vancouver.

It is proposed to establish a steel billet mill in connection with the Portland Rolling Mills at St. John, N.B. Such a plant would cost about $200,000 to construct, and another $100,000 would be required for its operation.

Lang Tanning Co., Berlin, have installed a complete system of electric drive for their factory, the electrical machinery being supplied by the Canadian General Electric Co. and the power plant by Goldie & McCulloch, Galt.

In 1905 the Granby smelter treated 650,000 tons of ore, and in 1906, with its two new large furnaces and with its six old furnaces enlarged, it should treat 85,000 to 90,000 tons of ore per month, or at least 1,000,000 tons for the year.

A new Singer Sewing Machine factory at St. Johns, Que., is now nearly completed, and represents an outlay of about $1,000,000. The plant covers 45 acres and has 18 separate buildings, all of modern steel construction and fireproof.

Cowan & Co., Galt, Ont., have just completed the almost complete equipment of Gardner's saw and planing mills, Galt, including a 42-inch sander, a 13-inch molder, a 42-inch band re-saw, a door clamp, a variety saw and a mortise machine.

Britton & Hedges, Boston, have placed a proposition before the town of Port Arthur regarding the location of a boiler tube and barbed wire works at that town. The company will employ 800 men and establish a $700,000 plant if a deal is completed.

Much interest is evoked by the announcement that the gross production of mines in British Columbia is estimated to exceed $20,000,000, more than twice the output of the Klondike. Last year the mineral production of the province was $18,977,359.

The Canada Foundry Co. have recently secured a large contract for the superstruction of Fredericton highway bridge. It is said that nearly 300 tons of steel will be required on the installation, and that it will be completed early in the Spring.

The Niagara Falls Foundry & Machine Co. has work enough ahead to keep it busy casting every day until April 1. The orders include the big pipe for the Ontario Power Co.'s elevator incline, between transforming station and power house.

Sheldon & Sheldon, Galt, are supplying induced draft apparatus to the Brunette Saw Mill Co., New Westminster, B.C., to the Pacific Coast Lumber Co., Vancouver, to the Bowman Lumber Co., Revelstoke, B.C., and to the Revelstoke Lumber Co., Revelstoke, B.C.

A company of English and American capitalists propose to construct a railroad from a harbor on the north shore of Lake Superior into the country north and beyond the height of land. They also propose to establish pulp wood mills in connection with the road.

Two diamond drills are to be used in developing the large coal areas near Nicola Lake. The Nicola Coal & Coke Co. own over 5 square miles of coal lands, and are directly on the proposed line of railway being built from Spence's Bridge to Nicola Lake.

A copper smelting plant is to be established at Wentworth Centre, N.S., at a cost of $300,000, according to a telegraphic report. There are several copper properties in Nova Scotia, and the establishment of the smelter should result in an increased production.

The Hanover Portland Cement Co.'s works are being remodelled and the output increased from 150 barrels a day to about 400 barrels. The plant is driven by electric power generated from water power at the company's own power plant on the Saugeen River.

A company is being formed at Godcrich to generate power for industrial purposes. It is proposed to dam the Maitland River and to construct auxiliary reservoirs to provide for the Summer drought. Cheap power would be assured for many manufacturing purposes.

The Lake Superior Company has recently made contracts with the Canadian Pacific Railway Company for 60,000 tons of steel rails, deliverable next year. The capacity of the Lake Superior Company for rolling steel rails is now fully taken up until about December 1, 1906.

The Smart-Turner Machine Co., Limited, Hamilton, have installed their duplex pump in the plants of Lumsden Bros., the Pure Milk Corporation, Andrew Langton, Brampton, Ont., John Harrison & Sons Co., A. Davis & Sons, Kingston, Northumberland Paper Electric Co.

East & Co., Toronto, are having a complete heating and ventilating system installed by Sheldon & Sheldon, Galt, Ont. So also are the following firms: London Machine Tool Co., Otis-Fensom Elevator Co., the Union Drawn Steel Co., and the Gurney-Tilden Co., all of Hamilton.

At Peterborough the factory of the Pre-Payment Meter Co. has been installed with the necessary machinery for the manufacture on a somewhat extensive scale of these meters. The work done in this plant will be an additional boom to the manufacturing interests of Peterborough.

The plan of the United States Steel Corporation to erect a plant in Canada has been shelved, notwithstanding reports that the question had again been taken up for consideration. The Pittsburg Dispatch says there is not any possibility of the scheme being gone on with this year.

The Maritime Coal & Railway Company have decided to establish an electric power plant at their mine, eight miles from Amherst, N.S., and an agreement has been entered into giving them the right to bring the power to Amherst and dispose of it for factory purposes there.

Western Canada is speculating on the probable move to be made by James J. Hill, the Canadian who has become a railway king in the United States. Rumors are rife regarding different pro-

jects he is said to be considering to build railways into the Saskatchewan wheat districts.

In the clearing house returns for the year is given the concrete amount of increase in the financial transactions for the year. The total for the year was $88,686,740, an increase of over $14,000,000 above 1904, which in its turn showed an increase of $8,000,000 over the total of 1903.

One of the largest mining deals reported in Ontario for some time has just taken place by the transfer of a copper property some 80 miles west of Port Arthur. The mine is known as the Tip Top Copper Mine, and is owned by Col. Ray of Port Arthur and Folger Bros., of Kingston.

H. H. Collier, solicitor for the Buffalo, Niagara & Toronto Railway, says that building operations will commence early in the Spring. The proposed line will run from Niagara-on-the-Lake to Buffalo, through St. David's and Bridgeburg, with a branch to St. Catharines and Welland.

By-laws to raise $20,000 for improvements for waterworks, $14,000 for electric light, and $12,000 for telephone improvements, and to give Whalen & Bowman exemption from taxes to build a marine drydock and machine shop, were carried at Fort William on January 1 by large majorities.

During the twenty-one months the Dominion Iron & Steel Co.'s blast furnace No. 4 has been in operation, 143,650 tons of pig iron, or an average of 7,000 tons per month, has been produced. On the production of this one furnace the Government has paid the bounty, amounting to $223,000.

The Farrar Transportation Company at Collingwood have decided to build a 9,000-ton steel carrier for use on the Upper Lakes. The work will be done at the Collingwood ship yards, and the boat will be completed in the Spring of 1907. It will be one of the largest Canadian vessels on fresh water.

The Temiskaming & Northern Ontario Railway Company has virtually decided to dispose of surplus electrical energy along the first 120 miles of the road, to companies along the route. The railway will deal with companies rather than with individuals or municipalities, thus obviating the necessity of keeping many accounts.

The White Sewing Machine Company, with headquarters at Cleveland, Ohio, are negotiating with the town of Welland for a site where they propose to establish a manufacturing plant in Canada. If the deal goes through they will secure certain advantages from the town and in return will employ 300 workmen.

H. W. Petrie, Toronto, has now under way the taking of a photograph of every machine in stock. This is intended as an aid to the selling department, as intending purchasers can be supplied with an original photo of any machine as required. This enterprising move will no doubt meet with the approval of the firm's customers.

A number of employes of the N. Thompson Engineering Works have won a case against the assignee, whom they sued for wages for work done after the assignment, and done at the instance of the assignee. The case turned on the adoption by the creditors of a resolution approving the action of the assignee in keeping the men at work.

The Dominion Iron and Steel Company has secured a second contract for rails from the G.T.R., aggregating 37,000 tons. Delivery on the new contract will begin the first of the year, when the I.C.R.'s 25,000-ton order will be completed. It is also said that the steel company has secured a large order for rails from the C.P.R.

Automatic feed pumps have recently been installed by the Smart-Turner Machine Co., Limited, Hamilton, in the new works of H. K. Wampole & Co., Perth, also Pennington & Bryan, Windsor, as well as a full equipment of pumps ordered by the Canada Glue Co., Brantford, who are putting up one of the most up-to-date glue factories in America.

Boynton & Plummer, Worcester, Mass., U.S.A., manufacturers of drilling machines, shaping machines, portable forges, bolt cutting machinery, etc., have moved from 52 Lagrange street to No. 54 Hermon street, Worcester, where they have more commodious quarters and better facilities for conducting their increasing business. This firm has a large and growing export trade.

The Rothschilds have taken a trial shipment of Cobalt ore for their smelters in England. They are considered the largest smelters of precious metals in the world and their purchasing of Cobalt ore should mean much to that camp. The Government is considering the advisability of erecting sampling works at Cobalt, for the convenience of miners.

The McLaughlin boiler shop, St. John, N.B., has been reopened, after several years' idleness. It has been leased to Alex. Wilson, mechanical engineer, and James O'Donnell, boiler maker, who have the sub-contract for supplying the iron work for the I.C.R. A company will be formed and about 50 men given employment in building boilers and in a machine shop to be established.

The suggestion that the Government should nationalize the harbors of Fort William, Port Arthur, Port Colborne, Kingston, Montreal, Quebec, St. John, Halifax, Sydney, Vancouver, and the Pacific coast outlets of the Grand Trunk Pacific and the Canadian Northern gives definite form to ideas that have been in the minds of many practical men who are interested in commercial and industrial expansion.

Allis-Chalmers-Bullock, Limited, Montreal, have made contracts for the electrical equipment of the Keewatin Flour Mills Co., Keewatin, the Ogilvie Flour Mills Co., Fort William, and the Western Canada Flour Mills Co., St. Boniface, Man., aggregating 4,000 horsepower. The motors range from 500 horse-power downwards. The entire equipments are under construction at the shops in Montreal.

The Economical Manufacturing & Supply Co., Limited, 173 Queen street east, Toronto, manufacturers of the well known Canada graphite, have about completed alterations to their premises, giving them additional room. This firm has recently been appointed Canadian agents for the products made by the New York Belting & Packing Co., Limited, New York, whose name is a household word among the engineers.

Two important announcements were made by representatives of the Lake Superior Corporation before the Tariff Commission at its recent sitting at the "Soo." One was that a coke plant would be built to supply the coke for use in connection with the steel plant, and the other that the directors had authorized the construction of open-hearth blast furnaces for the manufacture of steel for rails and structural purposes.

A society was organized recently at Galt by A. R. Goldie, of the Goldie & McCulloch Company, with a membership of 50 active men, the object being the beautifying of the town. Planting of trees, flower beds, vines, etc., will be particularly encouraged, besides the making of lawns, hedges and boulevards. The guild is not intended to be confined to Goldie & McCulloch men, but all citizens interested in making Galt homes and town prettier are invited to join.

A conspicuous departure in the lighting of canals is that of the Welland canal near St. Catharines, Ontario. Over 600 A.C. series arc lamps have been provided by the Canadian Westinghouse Company and these have been in operation for the past few months and have given splendid service. This installation as a whole redounds great credit to the Ontario Government, as well as to the consulting engineer, Mr. R. J. Parker, under whose direction the complete plant was installed.

The Ingersoll-Rand Company announce that they have secured exclusive control of the product of the Imperial Pneumatic Tool Company, with shops at Athens, Pa. The line of Imperial tools is well known and complete, including pneumatic hammers, drills, riveters, reamers, hoists and plug drills. The Ingersoll-Rand Company are manufacturers also of the Haeseler pneumatic tools and the public is now offered the choice of these two distinct lines of tools of established merit.

Grand Trunk Railway engineers are at Port Huron preparing the ground for the power house to be used in furnishing electric power for the tunnel. The building will have a frontage of nearly 200 feet and will extend back 300 feet. All of the cables leading to the tunnel will run down the shaft which was sunk over the property when the tunnel was constructed. The work of building the machinery has been begun by the Westinghouse Company, and will be ready as soon as the necessary building is erected.

Special machinery being added to the works of various companies recently by the Smart-Turner Machine Co., Limited, Hamilton, includes a hand-power traveling crane for the Forwell Foundry Co., Berlin, an automatic receiver to be placed in the plant of the Sudbury Building Supply Co., an independent jet condenser for the new works of the Jenckes Machine Co., St. Catharines, a brewers' air pump for Grant's Spring Brewing Co., and a tumbling barrel for the new and up-to-date plant of the Ingersoll Nut Co.

There is every indication of the reawakening of the mining industry in the northwestern portion of Ontario. The

Northern Development Co., for example, which has quietly been doing hand work for several years in the Rainy River district, is now preparing to operate on an extensive scale. They recently purchased from Allis-Chalmers-Bullock, Limited, Montreal, a complete mining plant including boilers, air compressors, rock drills, hoisting engine, pump and a large quantity of miscellaneous mining equipment.

Free Souvenir.

Readers of Canadian Machinery will be presented with a small barometer, mounted on a card, by the Berlin Electric Manufacturing Co., Berlin, Ont., by sending their name on a post card and mentioning this paper. This makes a useful article and is free to every reader.

Fiftieth Anniversary.

In commemoration of fifty years of successful business career, the J. C. McLaren Belting Co. are sending out an attractive paper weight representing a pile of ten gold pieces (twenty dollar size). In Canada but few firms have celebrated a golden anniversary, and the fact of this firm having reached the half century mark at once places it in a class as pioneers of Canadian industry.

Smith's Falls New Foundry.

Smith's Falls is to have a new iron stove foundry, which will be erected next Summer. The promoters of this new industry are Mayor Foster, Dr. Gray and John McEwen, all well-known business and financial men in town. A joint-stock company, with a paid-up capital of $30,000 is being organized. The building will cost $15,000, and will be modern in every respect. All kinds of stoves will be manufactured, and it is proposed to start with a staff of from 20 to 25 moulders.

Canada Chemical Co. Extending.

The Canada Chemical Co., of London, have undertaken important extensions in their works, included in which is the building of a large new chemical plant. Building operations will be started early in the Summer. The company has recently secured some valuable mining properties, and it is for the purpose of utilizing their ores that the acid works will be operated. The proposed location is in a Central Ontario point, north-east of Toronto, which will be convenient to the source of ore supply. Sulphuric acid and similar acids and chemicals will be produced by the most recent and advantageous patent processes. In addition to the new acid works, it is understood the company will continue to operate the present plant in London, and their distributing warehouses at Toronto and other points.

A New Electrical Industry.

A plant of considerable importance to the Canadian manufacturing trade has been opened up in Berlin, Ont., by the Berlin Electrical Manufacturing Co. for the purpose of manufacturing high grade dry cells, flash light and novelty batteries, the trade name of these being "Best." An expert has been secured who has had nine years' experience in the dry cell business, having been connected with the largest dry battery manufacturers in America. A new system in the manufacture of dry cells has been adopted whereby they have been enabled to turn out a dry cell of absolute uniformity. Their improvement increases the life of the batteries, which are guaranteed not to deteriorate more than 15 per cent. in one year on the shelves, the purest chemicals and filtered water being used.

The standard size No. 6 battery, 2½ by 6 inches, will give 22 to 25 amperes at 1.6 volts and will melt a 10-ampere fuse on a short circuit in less than 30 seconds. The larger No. 7 battery, 3 by 7 inches, shows 30 amperes and is particularly adapted for ignition purposes. Although on the market but a short time the "Best" batteries have met with a good reception and have many friends.

New Works, Armstrong Bros. Tool Co., Chicago.

The accompanying engraving gives a capital exterior view of the new plant of Armstrong Bros. Tool Co., Chicago. The site is an excellent one, the ground having a frontage of 200 feet on the Chicago & Northwestern Railway and 216 feet on Francisco Ave., corner of Carroll Ave. The main building is three storeys and basement in height and is of standard mill construction with stairways and elevators enclosed in brick shafts fitted with fireproof automatic closing doors.

Armstrong Bros'. Tool Works.

The dimensions of the main building are 175 x 60 feet, with one storey annex 175 x 30 fe t. The location and arrangement of the buildings is such that perfect light and ventilation is secured. Much new machinery of the latest type has been installed. Steel pulleys with pressed steel hangers and roller bearings are used exclusively. Iron and sheet steel are used wherever possible in partitions, benches, stands, drawers, packing tables, stock racks, and shelving, very little light wood being visible.

The assembling, stock and shipping departments are especially remarkable in this respect and comprise one of the most complete and well designed sheet steel fixture installations in the United States.

We hope later on to show some interior views of this plant, which will prove of general interest.

Robb Engineering Co's Growth.

At Amherst, during the first week in January, the Robb Engineering Company entertained at dinner, at the Terrace Hotel, their travelers, representatives, foremen and superintendents of departments. President D. W. Robb presided, and at length he outlined the origin and progress of the company. Among those present were Mr. J. F. Porter, of Winnipeg, and Mr. Wm. McKay, of Toronto. One of the pleasant events of the evening was the presentation to D. W. Robb of a handsome clock and candelabra by the members of the selling staff. Mr. Robb, in referring to the company's history, said that on May 9, 1865, over forty years ago, the first sod was turned for the erection of a small foundry, which has since grown into the works of the Robb Engineering Company. The original site consisted of two acres, and the first building to be erected was the foundry, 30 x 60 feet, with a monitor roof. In addition a small machine shop, about 30 feet square, with engine and boiler house in the rear, was built. The first engine and boiler used for the machine shop was about 15 horse-power. Since then the growth of the company has been marvelous. New and extensive works have been established at Amherst and at Framingham, Mass., and branches opened at Montreal, Toronto and Winnipeg.

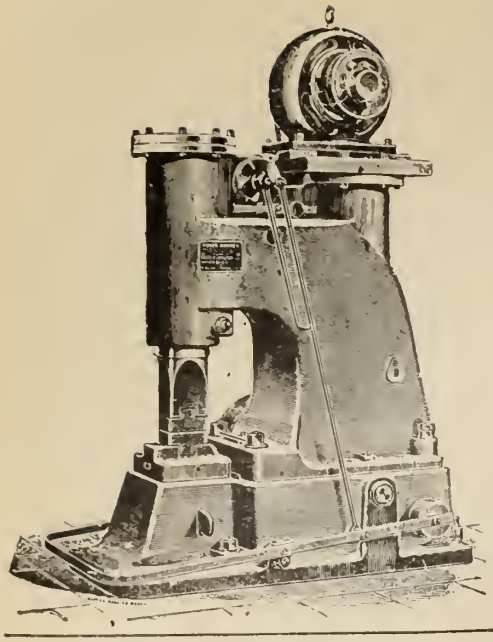
MAY 2 1906

An Important Centre.

When the Tariff Commission was in session at Amherst, N.S., the members were addressed by D. W. Robb, president of the Robb Engineering Company, and vice-president for Nova Scotia of the Canadian Manufacturers' Association. He spoke of Amherst as one of the best examples in Canada of what prosperous factories can do for any locality. He pointed out that the business passing through Amherst station exceeds that at any point on the line except Montreal, St. John and Sydney, and if the Commission could be instrumental in developing business over the whole Intercolonial in like proportion, the question of its deficits would be solved. He claimed that the protection



PILKINGTON'S POWER HAMMERS

PETER PILKINGTON, LTD. 75a, Queen Victoria St., LONDON, E.C.

and inducement of a reasonably protective tariff are a great incentive to investment in industries, and a strongly protective tariff would encourage larger investments in Nova Scotian industries. Expressing his personal views, he emphasized the fact that the present 25 per cent. duty had not prevented manufacturers of other countries, especially the United States, from sending nearly half a million dollars' worth of engines and boilers into Canada yearly for the last three or four years. He considered the recommendation of the Canadian Manufacturers' Association for increasing the duty on engines and machinery of that class to 35 per cent. in the interest of the whole country.

At the sitting of the Tariff Commission at Three Rivers recently, Mr. G. R. Duncan, manager of the Montreal Pipe Foundry, pleaded for an increased duty on iron pipes. He maintained that Scotch and English pipe could be put down in Canada at such rates as to cripple the industry in Canada, the reason being that they had advantages in the matter of pig iron, wages, freight rates, and fuel. In the matter of wages, he contended that in Canada we pay the American rates. Men in their works received $1.75 to $2.25 per day, while the same class can be had in Britain for $1.35 to $1.50 per day. Instead of $5.35 per ton, Mr. Duncan pleaded for a minimum of duty of $8, the cost of a ton of pipe in England being $22. Mr. Gelineas, manufacturer of chains and snow shovels, and Mr. O. Carignan, manufacturer of paints from Canadian ores, pleaded for increased protection in their respective trades.

PRACTICAL MECHANICS.

By W. H. Raeburn.

(*Continued from page 57*)

which enters so largely into the construction of machines of various kinds. We shall endeavor to make clear the methods of making calculations for speeds and loads of gears in our next article. We cannot, however, pass to that branch of the subject without making a few observations regarding bent levers.

A Mistaken Idea.

Some years ago an English bicycle manufacturer put on the market a crank as shown in Figure 3, which is a striking illustration of the fact that even reputable mechanics betray at times a lack of knowledge in elementary principles. The idea was to get the same effect as an 8-inch crank would produce, yet with the motion of a 6½-inch crank. A short examination in the light of the principle of moments will show the fallacy of such hopes. Let a pressure of 50 lbs. be exerted at (P), then the moment of that force about the centre of motion is clearly $50 \times 6\frac{1}{2} = 325$ in. lbs., the distance 6½ in. being measured at right angles to the line of direction of the pressure. By no means can we exert pressure at (P) so as to make the distance from the line along which the pressure acts to the centre of the axle greater than 6½ in., so that the peculiar style of the crank is of no avail so far as increasing leverage is concerned. When using a wrench we unconsciously carry out the idea suggested here. We apply the force at the greatest possible distance from the fulcrum, and at right angles to the lever, thus exerting the maximum turning moment.

MACHINERY BUYERS' DIRECTORY.

Readers of CANADIAN MACHINERY are invited to use this directory as a ready reference when seeking to buy any machinery or machinists' supplies. In it will be found a list of goods made by leading Canadian firms and by the principal firms in other countries who are devoting especial attention to the Canadian market. It is the intention of the publishers of this paper to issue a desk index for machinery buyers, and all advertisers are invited to send in full list of lines manufactured.

CONDENSED MACHINERY ADVERTISEMENTS.

Rates—25c. for twenty words or less; 1c. a word for each additional word.

AGENTS WANTED.

WANTED — Practical machinists, to act as representatives of CANADIAN MACHINERY in the shops they work in; liberal commission offered. Address Business Manager, CANADIAN MACHINERY.

MACHINERY FOR SALE.

FOR SALE—One 3-phase, General Electric Co. of Sweden, generator; 100 k.w., 500 v., 60 cyc., 7,200 alt.; complete with exciter and switchboard, on which are mounted volt meter and amin meter. Apply Sandford Furniture & Woodenware, Limited, Fenelon Falls, Ont.

FOR $650—Half value—one 40 h. p. engine; one 40 h. p. boiler, 50-ft. stack; 1¾ acres land; good house; mill building and stable; suitable for small factory; or will sell machinery separate; location, Hepworth, Bruce County. Write R. Murdoch, Sault Ste. Marie, Ont.

SITUATIONS VACANT.

WANTED—At once, a reliable man to take full charge of the Lucan electric light plant; must thoroughly understand Corliss engine; alternating current dynamo and wiring; nothing but an experienced man wanted; must be strictly temperate; married man preferred; write, stating wages and mail reference at once. Address H. Cook & Sons, Hensall Ont.

BUSINESS CHANCES.

FACTORY FOR LEASE—Suitable for large works; combination metal-working and woodworking; exceptionally good terms. Apply to Business Manager CANADIAN MACHINERY, Toronto.

MACHINE SHOP — Established 12 years; lathes, drills, grinders, etc.; patterns for 3, 6, 15 and 25 h p. gasoline engines; automobile engine patterns for 6, 12 and 16 h.p.; also several other patterns and engines in stock at present; repair trade paying big profits; in Canadian town of 45,000 inhabitants; must be sold at once on account of ill-health of proprietor; price about $3,000. Box 301, CANADIAN MACHINERY, Toronto.

MACHINERY WANTED.

MACHINERY WANTED—One second-hand boiler, 50 or 60 h.p.; one heavy planer and matcher, suitable for dressing hardwood; 20 feet 2 15-16" sh.ft. Thos. J. Hollis, Mount View, P.O.

WANTED — 75 horse power engine, second-hand or new; must be in first-class condition. Apply, stating price, with full particulars, Don Valley Brick Works, 36 Toronto St., Toronto.

IRON WORKS FOR SALE

Including Foundry, Machine and Boiler Shops, as a going concern. Located in Western Canada, doing good business and up-to-date plant. Apply to

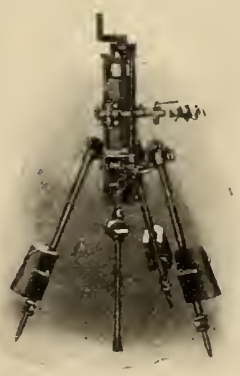
Expanded Metal and Fireproofing Co., Limited

100 KING ST. W. - - - TORONTO

"The valve arrangement is such that sticking is impossible. Been using your drill for three months and it has never given a minute's trouble"



"The rock we are removing is of a very hard nature and in this class of rock your drills are doing better work than we have had from other drills in rock of a far softer nature."

ROCK DRILLS
FOR
MINES, SEWERS, QUARRIES, Etc.

NATIONAL MACHINERY CO., Tiffin, Ohio, U.S.A.

Canadian Agents: H. W. PETRIE, Toronto, Ont. WILLIAMS & WILSON, Montreal, Que.

There are other Watchman's Clocks, but the pioneer of all is the

ECO MAGNETO

WATCHMAN'S CLOCK

Which is and always has been entirely constructed for magneto operation.

Similar devices, cheaply gotten up, operated by battery regenerators, are liable to faults of construction. The superiority of the Eco Magneto is easily proved.

It is approved by the National Board and all Underwriters.

is fully guaranteed for 5 years.

is installed on trial and subject to moderate cost when accepted.

Used by foremost Canadian firms and found entirely satisfactory.

ECO MAGNETO CLOCK CO., BOSTON MASS.

6 SIZES. 500 SOLD IN TWO YEARS.

ANY OLD THING WON'T DO FOR TUMBLING ANY MORE,

because any old way costs too much, so here's our Improved Oblique Tumbling Barrel, which does the work better and faster than any other. It is a self-cleaner, self-dumper; is quickly adjustable for easy or violent tumbling and is for wet or dry work. Catalog describes thoroughly.

SYLVESTER GASOLINE ENGINES

Marine and Stationary, are the best skilled labor can produce.

They are easy starting; they are simple and reliable; they will give full power in the coldest weather; they are built in sizes from 1½ to 32 horse power; they will run on gasoline, coal oil or distillates.

The SYLVESTER Engine inspires confidence because it is so simple in construction. It is the cheapest engine to buy because there is nothing to get out of order.

The SYLVESTER Engine is especially designed for wood-working plants or where cheap power is required.

Manufacturers—Write for Catalogue and our 1906 Calendar.

Taper Locomotive Reamers.

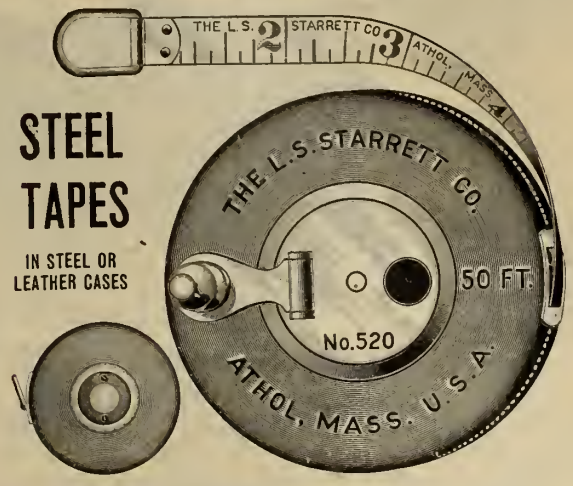
Only the highest possible class of material and the most up-to-date methods will be employed in making these REAMERS.

BUTTERFIELD & CO., - - ROCK ISLAND, P.Q.

STARRETT TOOLS

ARE THE STANDARD

FOR ACCURACY, WORKMANSHIP, DESIGN AND FINISH



STEEL TAPES

IN STEEL OR LEATHER CASES

In our tapes the figures denoting feet are smaller than those denoting inches. Two reasons for this :

This dissimilarity of figures materially lessens (in fact ought to entirely prohibit) the liability to erroneous readings that frequently occur through the uniformity of all figures in steel tapes of other makers.

The smaller figures, denoting feet, allow the graduation line under each to be plainly visible, instead of being obliterated by the usual larger figure.

Graduated in feet, inches and eighths of an inch, or in feet, tenths and hundredths of a foot.

SEND FOR FREE CATALOGUE, No. 173, OF FINE MECHANICAL TOOLS.

TECHNICAL BOOKS

COMPRESSED AIR.

ITS PRODUCTION, USES AND APPLICATIONS.

BY GARDNER D. HISCOX, M. E.

Author of "Mechanical Movements, Power, Devices, and Appliances," etc., etc.

Bound in Cloth - - - PRICE, $5.00

Half Morocco Binding, - - PRICE, $6.50

A complete treatise on compressed air, giving the physical and operative properties from a vacuum to its liquid form. The thermodynamics, compression, transmission, expansion, and uses of compressed air for power purposes in engineering, mining and manufacturing work are treated.

Containing special chapters on air compressors, air motors, air tools, air blasts for cleaning and painting; the sand blast, air lifts for pumping water, oils and acids, submarine work, aeration of water, railway appliances and propulsion; the air brake, pneumatic tube transmission, refrigeration and cold rooms. The hygiene of compressed air, its liquefaction and phenomena, including forty tables of the physical properties of air, its compression, expansion and volumes required for various kinds of work, and a list of patents on compressed air from 1875 to date.

The tables included cover most of the relations of our atmosphere and its contained moisture in its various conditions from a vacuum to its highest pressure and power for work; its final liquefaction and the phenomena of extreme cold.

The tables are fully explained and the formulas given and worked out. The thermodynamic formulas for air compression and expansion are given in a precise form with full explanations and examples, so that any one can solve the problems in air compression, transmission, expansion and the power required in atmospheric work.

Large Octavo. 820 Pages. 545 Illustrations.

HOW TO BECOME A

Successful Electrician

BY PROF. T. O'CONOR SLOANE.

200 Pages. Illustrated.

PRICE, $1.00

IT is the ambition of thousands of young and old to become Electrical Engineers. Not every one is prepared to spend several thousand dollars upon a college course, even if the three or four years requisite are at their disposal. It is possible to become an electrical engineer without this sacrifice, and this work is designed to tell "How to Become a Successful Electrician," without the outlay usually spent in acquiring the profession.

CONTENTS.

CHAPTER I.—Introductory. CHAPTER II.—Mathematics. CHAPTER III.—Physics. CHAPTER IV.—Chemistry. CHAPTER V—Electricity at Home. CHAPTER VI.—Mechanical Engineering. CHAPTER VII.—Drawing. [CHAPTER VIII.—Teachers. CHAPTER IX.—Electrical Factory Work for Students. CHAPTER X.—College Education. CHAPTER XI.—Steam Engineering. CHAPTER XII.—The Manufacturing Engineer. CHAPTER XIII.—The Constructing Engineer. CHAPTER XIV.—The Station Engineer. CHAPTER XV.—Inventing. CHAPTER XVI.—Original Investigation. CHAPTER XVII.—Success. CHAPTER XVIII.—Reading. CHAPTER XIX.—Ethics.

MODERN MACHINE SHOP TOOLS.

Their Construction, Operation and Manipulation, Including both Hand and Machine Tools.

BY W. H. VANDERVOORT, M. E.

Large 8vo 555 Pages. 673 Illus. Bound in Cloth.

PRICE, $4.00

An entirely new and fully illustrated work, treating the subject of Modern Machine Shop Tools in a concise and comprehensive manner. The work is logically arranged; the various hand and machine tools being grouped into classes, and description of each is given in proportion to their relative importance. The illustrations represent the very latest tools and methods, all of which are clearly described. Each tool is considered from the following points: FIRST—Its construction with hints as to its manufacture. SECOND—Its operation proper manipulation and care. THIRD—Numerous examples of work performed.

CONTENTS.

The Hammer and Cold Chisel; the File and Filing; Scrapers and Surface Plates; Standards of Measures; Calipers; Gauges and Indicators; Rules, Squares and other Small Tools; Drills; Reamers; Screw Threads Tap and Dies; Drill and Tap Holders; Mandrels; The Lathe: The Lathe in Modified Forms; Lathe Tools; Chucks and Drivers for Lathe Work; Lathe Work Between Centers; Lathe Work on Face Plate Chuck and Carriage; Boring and Turning Mills; Planing and Shaping Machines; their Tools and Attachments; Planer and Shaper Work; The Slotting Machine and Key Seater; Milling Machine; Milling Machine Cutters; Milling Machine Work; Gear Cutters and Gear Cutting; Drilling Machines and Drilling Work; Grinding Machines and Grinding, Hardening and Tempering; Fastenings, Gearing; Belting and Transmission Machinery; Miscellaneous Shop Equipment and Conveniences; Useful Data and Tables.

Electricity Simplified

By PROF. T. O'CONOR SLOANE.

158 Pages. Fully Illustrated.

PRICE, $1.00.

THIS work is the simplest ever published on the subject of Electricity, and does something not hitherto accomplished. Electricity is in many respects unexplained by the scientist; to the ordinary man it is all a mystery. The object of "Electricity Simplified" is to make the subject as plain as possible, and to show what the modern conception of electricity is; to show how two plates of different metals immersed in acid can send a message around the globe; to explain how a bundle of copper wire rotated by a steam engine can be the agent in lighting our streets; to tell what the volt, ohm, and ampere are, and what high and low tension mean; and to answer the questions that perpetually arise in the mind in this age of electricity. The theories of contact action, of lines of force, magnetic permeability, correlation and conservation of energies, and the most modern aspects of the science are given so that the work is a true presentation of the most advanced views of science upon the great development of the day. By illustration of original design and scope, and by mechanical analogies, the subject is made exceedingly simple.

—CONTENTS.—

CHAPTER I.—The Ether, Electricity, Force and Energy, Mass and Weight. CHAPTER II.—The Electric Charge, Potential, The Dielectric, Positive and Negative Electricity, Contact Action, Electrostatic Lines of Force, The Leyden Jar. CHAPTER III.—The Electric Current and Circuit, Relations of Electromotive Force, Resistance and Current, Velocity of Electricity. CHAPTER IV.—Fundamental Units and the Relations Between Electrostatic and Electromagnetic Units, Practical Units; the Volt, Ohm, Coulomb and Ampere, Electric Force, Work and Energy, Chemistry of the Current. CHAPTER V.—The Magnetic Circuit and Electromagnetic Lines of Force, Magnet and Ampere's Theory. CHAPTER VI.—Electromagnetic Induction and Action of Currents Upon Each Other, The Induction Coil and Its Application. CHAPTER VII.—The Galvanic Battery, The Electrotype and the Locus of its Potential Difference, Polarization and Local Action, Different Examples of Batteries, The Arrangement and Action of Batteries, Storage Batteries. CHAPTER VIII.—Dynamos, Motors, Transmission of Power. CHAPTER IX.—The Telephone and Microphone, Electric Lighting, The Electric Telegraph, The Dangers of Electricity, Conditions for Receiving a Fatal Shock.

Merrell Motor and Engine Driven Machines

Motor Drive

These machines, which are to be had in four sizes, will do far more rapid work, both in threading and cutting off, than any other combined machine on the market. The gear enclosing the dies is completely housed from dust and chips. The rheostate is inside of the base and the starting lever in a convenient location on the side of the machine. The motor used is constant, the variation in speed of the machine being obtained by means of an idler pinion and nested gears.

Illustrated Catalogue sent on request.

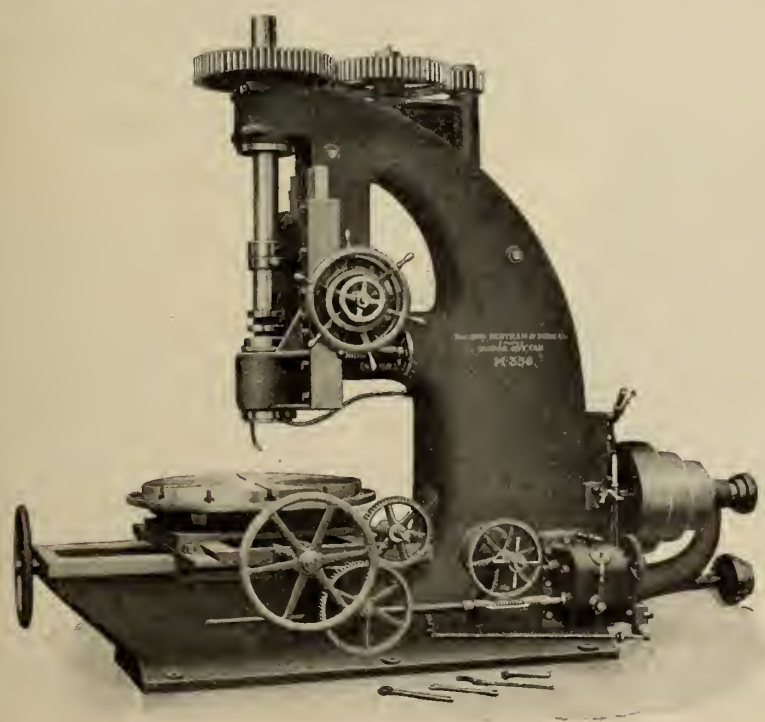
The Bertram Vertical Milling Machine



Has a spindle 5 inches diameter

and a combination of strong points which makes it the most powerful machine of its kind built. Attention is called to the powerful train of gear, making it possible to obtain a cutting force of 21,000 lbs. at the circumference of a milling cutter 5 inches in diameter. It has quick-change gear, all of steel. The driving cone has three steps for a 6-inch belt and has 12 changes of speed. All feed motions are conveniently located so that the operator need not leave the working side of the machine. The spindle has a vertical movement. The circular table is provided with power rotary, cross and longitudinal feeds, which are reversible as well as hand adjustment. For fuller information regarding this or any other of the Bertram lines of machine tools, write to

Sylvester Gasoline Engines

Are the best that skilled labor can produce.

They are easy starting; they are simple and reliable; they will give full power in the coldest weather. Made in sizes from 4 to 32 horse power in portable snd stationary and from 1½ to 12 horse power in marine. They will run on gasoline, coal oil or distillates.

The SYLVESTER Engine inspires confidence because it is so simple in construction. It is the cheapest engine to buy because there is nothing to get out of order.

The SYLVESTER Engine is handsome in appearance, substantial in construction, marvelous in simplicity, unequalled for effectiveness and durability.

THE HIGHEST AND MOST PERFECT TYPE OF GASOLINE ENGINE BUILT.

If you require to purchase, write for Catalogue and our 1906 Calendar. We will then send our Travelling Salesman to you

Modern Canadian Manufacturing Plants.

ARTICLE XIII.—The John McDougall Caledonian Iron Works Co., Limited, Montreal.

ONE of the oldest established and best known of Canadian manufacturers is the John McDougall Caledonian Iron Works Co., Montreal, which firm has been in existence since 1853, when it was first launched by the late John McDougall. Since 1892, new and larger steel, frame and brick buildings have been erected throughout the entire plant.

Fig. 1—The John McDougall Caledonian Iron Works, Montreal—Exterior of Boiler Shop.

additional ground having been acquired for that purpose, and machinery of greater capacity has been installed, until to-day the equipment will compare favorably with any in the same line of engineering business.

Boiler Making.

The boiler making department is shown in illustrations 1 and 2, where exterior and interior views of the boiler shop are given. This building has a floor space of 160 x 60 feet, and is completely equipped for the manufacture of boilers of all types, marine, plain tubular, Lancashire, locomotive or water tube, also flumes, penstocks, tanks, stacks, and plate work of all descriptions. This shop is equipped with a traveling crane of 25 tons capacity, which travels the entire length of the shop. At the farther end is the hydraulic riveting plant, which is served by an independent traveling crane, with power hoisting and lowering attachments. This crane is placed in the tower so that boiler shells thirty feet in length may be lifted vertically while being rivetted. Compressed air tools and appliances form an important part of the equipment of this department for lifts, rivetting, drilling, caulking and chipping, the air being supplied by a compound, steam operated, two-stage Ingersoll-Seargant compressor.

In the rear of the boiler shop are two extensions. One of these is the forge shop, with a floor space of 60 x 50 feet, arranged for seven forges, with steam hammer and the necessary cranes. The other extension, with a floor space of 110 x 44 feet, contains the boiler and engine supplying power to the machinery in this department and the air compressor. The remainder of this extension is used as a flange shop, where boiler heads and plates are flanged and formed. This shop also contains the hydraulic press and furnace, with punches and forming dies, for the manu-

facture of the Alexander car replacer, and for forming pressed steel boiler manhole rings, covers, guards, side brackets, flanges, etc.

Metal Casting.

Engraving No. 4 gives an interior view of the foundry, which has a floor space of 140 x 90 feet, with a gallery 22 feet wide on one side, used for the storage of foundry supplies; and charging floor for cupolas. It is equipped with three cupolas, 48, 34 and 24 inches inside diameter, and two No. 7 Sturtevant blowers.

Fig. 2 The John McDougall Caledonian Iron Works, Montreal—Interior of Boiler Shop.

The main floor is served by three jib cranes of fifteen tons capacity each. This foundry is well lighted and airy, and has excellent facilities for turning out large quantities of loam, dry sand or green sand castings, and has turned out pieces weighing up to 25 tons. In rear of the foundry is an inclined driveway, allowing the raw material, pig iron, scrap and coke to be teamed on to the gallery floor. Owing to the foundry's location alongside the Lachine Canal, the floor is only a few feet above the water level and water-tight pits had to be provided to take care of cylinder and other deep work, and to handle pipes, rolls and pieces requiring to be cast on end.

The Machine Shop.

The interior of the machine shop is shown herewith, which has a floor space of 140 x 90 feet, with a gallery 22 feet wide on one side and 28 feet wide on the other. This shop also has a traveling crane of 25 tons capacity, serving its entire length. In the foreground of the cut are the large tools—the chucking lathe, with a capacity for turning a pulley or wheel 20 feet in diameter, and the large planer, which will plane a piece 7 feet high, 7 feet wide and 20 feet long. About the centre of the shop, on the main floor, is the boring mill, which was nominally designed to bore, turn and cut keyseats of pulleys up to 16 feet in diameter, but its range is very elastic, and by means of extensions and additions is used for many other operations than originally intended. To the left of the boring mill is a 67-inch "Gleason" gear cutter, or planer. This machine cuts gear teeth in wood, iron or steel, spur or bevel; its nominal capacity is 67 inches diameter, but it has been used to cut the wooden cogs of core wheels 7 feet in diameter and 14 inches face. In rear of the "Gleason" machine are two rotary cutter machines, used on smaller work. The smaller machines, lathes, drills, etc., are grouped below and in the galleries.

This shop has special facilities for mill work of all kinds, shafting, gearing, pulleys, rope wheels, etc., pulp mill apparatus, starch and glucose work, machinery for rolling mills, sugar refineries, etc. In rear of the machine shop is an extension 60 x 56 feet, two storeys high. On the lower floor is located the power plant, two 75 horse-power water wheels, operating the machine shop, pattern shop and foundry. The upper floor is used as a pattern shop and woodworking department, and is equipped with the necessary lathes, saws and planers. Adjoining this extension is a one-storey brick building, containing the boiler, blowers, etc., for heating these buildings by hot air.

The office is located at the corner of

William and Seigneurs streets. This is a two-storey brick building, 35 x 35 feet, the lower floor of which contains the general and superintendent's office, and the upper floor the general manager's office, sales, engineering and estimating departments. To the left of the office is a three-storey brick building, 80 x 70 feet, used for pattern storage.

Lines Manufactured.

While these works are operated on general engineering and contracting lines, for manufacture and sale of the Worthington turbine pump, steam, belt or electrically driven, and about 80 of these pumps are now in successful operation in sizes from 1 1-2 inches to 16 inches, and under the most varied conditions throughout the Dominion.

Among the other specialties that are manufactured by this company may be mentioned: pressure and gravity filters in connection with the New York Continental Jewell Filtration Co., of New York; wood pulp grinders, centrifugal for manufacture and sale of the Worthington turbine pump, steam, belt or electrically driven, and about 80 of these pumps are now in successful operation in sizes from 1 1-2 inches to 16 inches, and under the most varied conditions throughout the Dominion.

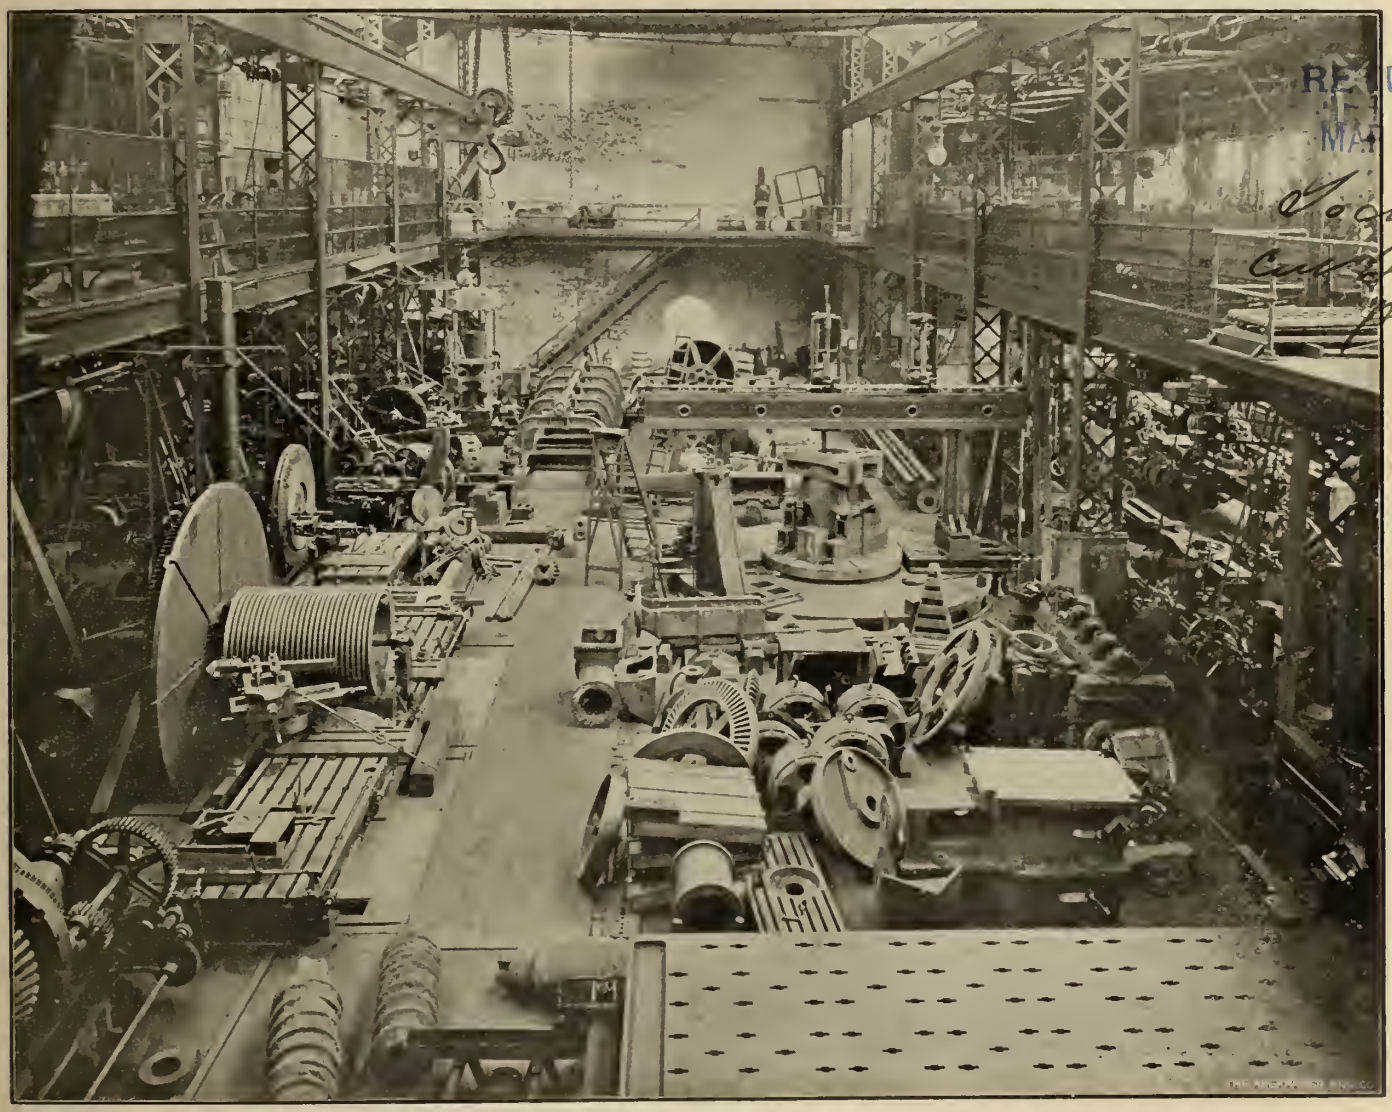
Among the other specialties that are manufactured by this company may be mentioned: pressure and gravity filters in connection with the New York Continental Jewell Filtration Co., of New York; wood pulp grinders, centrifugal and diaphragm screens in connection with the Baker & Shevlin Co., of Saratoga, N.Y.; Doble impact water wheels in connection with the Abner Doble Co., of San Francisco, Cal.: the Tonkin water tube boiler in connection with the Oil Well Supply Co., of Oswego, N.Y.; belt conveying machinery in connection with the Robins Conveying Belt Co., of New York; pressed steel car replacers in connection with the Alexander Car Replacer Co., of Scranton, Pa.

COAL MINING IN SOUTHWESTERN ALBERTA.

By Oliver Hall, M.Sc.

THOUGH an extensive coal field has long been known to exist in Southwestern Alberta, it is only within the last three years that it has been largely exploited. Already, however, three companies in this field are on a large and firm shipping basis, and bid fair to soon rival their older rival, the Crow's Nest Co., on the western side of the Crow's Nest Pass. They are supplying a considerable percentage of the British Columbia smelter coke, and at least one-half of the steam coal of the prairies. These three are the Canadian-American, the West Canadian, and the International Coal & Cooke Companies.

The Canadian-American was the first



RETURNED

to open up, operating the Frank mine at Frank, of landslide fame.

The successful attempt of Turtle Mountain to go tobogganing here in April, 1903, caused for a time a cessation of all mining, burying one-half the town of Frank, destroying several miles of built and projected railroad, and leaving a block of nearly two and a half square miles of rock debris. The management, with great energy, however, soon recommenced operations, and with

day, but is only developing. It has two seams over 15 feet in thickness, both admirable steam and domestic coal. Its Lille colliery, six miles north of Frank, is on a steady shipping basis of six to nine hundred tons of coal and coke. It operates its own railway, has an up-to-date sizing and picking tipple, and a complete coking plant. It has just completed the first coal washer in Western Canada. This, with its three batteries of Belgian mechanically operated re-

It would seem that the Southwestern Alberta coal field in the vicinity of Frank must, within a few years, be the centre of a tremendous industry. (A large zinc smelter has been built in Frank. Since two tons of coke are needed to smelt one of ore, it is a natural centre. The meteoric settlement of the prairie is causing a tremendous demand for both domestic and steam coal. While the domestic demand can be largely met by the unlimited lignite fields at Souris,

RETURNED

To Montreal
Our Book 48
page 19

Fig. 4 The John McDougall Caledonian Iron Works, Montreal—Interior of Foundry.

the exception of a period of partial closure on account of gob fires, have continued steady shipments of from four to eight hundred tons per day.

The West Canadian collieries, an amalgamation of capital largely French, are operating only at Bellevue and Lille, but have very extensive holdings, over thirty thousand acres in all, with coal outcrops through every parcel. The Bellevue colliery, two miles east of Frank, is outputting only 250 tons per

tort ovens, gives it perhaps the best coking plant in the west.

The International Coal & Coke Co. have opened up large collieries at Coleman, six miles west of Frank. They have a first-class plant in every way, outputting about 1,000 tons daily and capable of at least 2,000. They have both compressed air and electric haulage, a very extensive tipple, and over two hundred bee-hive coke ovens.

Lethbridge, Edmonton and elsewhere, for steam purposes, it is to the Southwestern Alberta field that the west must look. Coal alone is already creating a freight traffic on the Crow greater than that on the main line, and with the completion of the new railways, it must treble. The Canadian Northern has already placed orders, and the Grand Trunk Pacific, when constructed, will greatly increase the demand.

Steam Turbine Pump at Waterloo, Ont.

AN interesting pumping installation is that recently installed at the municipal pumping plant at Waterloo, Ont., of which some illustrations are presented.

The pumping unit is of the centrifugal type and is driven by a De Laval steam turbine. The entire outfit was manufactured by Messrs. Greenwood & Batley, of Leeds, England, and installed by the D'Olier Engineering Co., of New York and Philadelphia. The pump is designed for a service of 2,000,000 imperial gallons, each twenty-four hours against a total head of 218 feet. It will be seen from the cut that the pump part of the unit really consists of two separate pumps, these being connected by pipe bends so as to add their effects. The entire outfit is mounted on a single subbase and is consequently self-contained. The construction details of the De Laval steam turbine are quite generally known. However, the De Laval pump is possibly not so familiar.

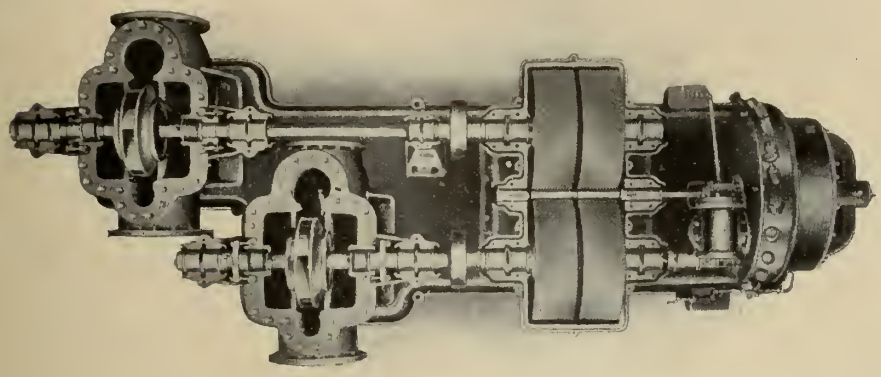

Fig 1—Pump Case and Gear Case Covers Removed.

The cut shows the De Laval pump with the upper part of the pump and gear cases removed, showing clearly the running parts. It will be noted that the pumps are equipped with ring oiling bearings and that the packing boxes are made separate from the bearings, a feature which has proven extremely desirable in practice, as has also the split pump case arrangement, which thus allows access to the interior of the pump without disturbing the piping connections.

The chart given herewith shows the performance of the pump, and it will be noted from this that the duty secured is in the neighborhood of 75,000,000 foot pounds per 1,000 pounds of dry steam, and that the efficiency of the pump end of the unit is only slightly less than 70 per cent.

The entire pumping set is a very compact one and occupies over all a space of 14 feet 3 inches long by 6 feet 4 inches wide, and a height less than 5 feet.

The pump is provided with centrifugal governor for regulating the speed and it will be seen from the characteristic curve of the delivery and pressure produced by the pump, that even with all valves shut on the discharge, the pressure will not run up dangerously, the shut-off pressure for this pump being equivalent to a height of 288 feet.

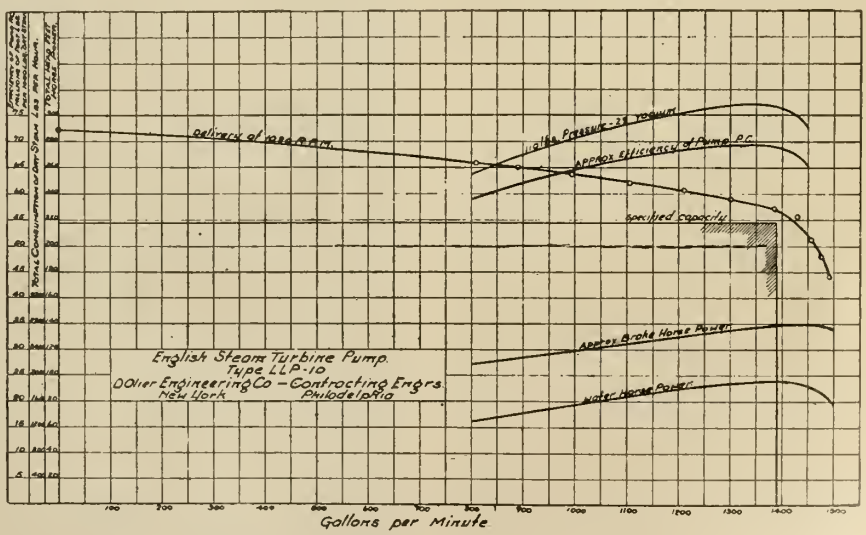

Fig. 3—Operation of Steam Turbine Pump, Waterloo, Ontario.

INTERESTING STEAM ENGINE TEST.

AN interesting official fifteen hour test of one of the nine twin vertical-horizontal Reynolds Corliss engines, cylinders 42 inches and 86 inches by 60 inches, which have been in operation at the 59th Street Station of the Interborough Rapid Transit Co., New York City, since 1902, was concluded December 15. The tests were conducted by the Interborough Rapid Transit Co. and representatives of the Allis-Chalmers Co. as a final determination of the fulfillment of the builder's guarantee, and formally provided for in the original contracts.

How well the tests of engine No. 8, which was selected as representing all the engines installed, fulfilled the claims made for it, may be readily ascertained from the following data giving a synopsis of the completed tests.

As per agreement, on account of the impossibility of keeping a constant load, the power was determined by the readings of tested integrating wattmeters. These readings were reduced to I.H.P. by running the generator as a synchronous motor; adding the electrical input to the switchboard readings when developing power, to obtain the power exerted by the engine.

The result of the test so made, under conditions approximating the contract requirements of 7,500 H.P., 75 r.p.m., 175 pounds steam pressure and 26 inches vacuum, was a consumption of 11.96 pounds of dry saturated steam per I.H.P. hour, or well within our guarantee of 12.25 pounds. The steam consumption per k.w. hour at the switchboard was 17.34 pounds.

Duration	15 hours.
Load	5079.2 K.W.
Friction and Generator losses	417.3 K.W.= 559.41 H.P.

Total Load	5496.5 K.W.
I.H.P.	7365.3 H. P.
R.P.H	75.02
Steam Pressure	175.18 lbs.
R.H. Receiver	19. 1 lbs.
L. H. Receiver	19.27 lbs.

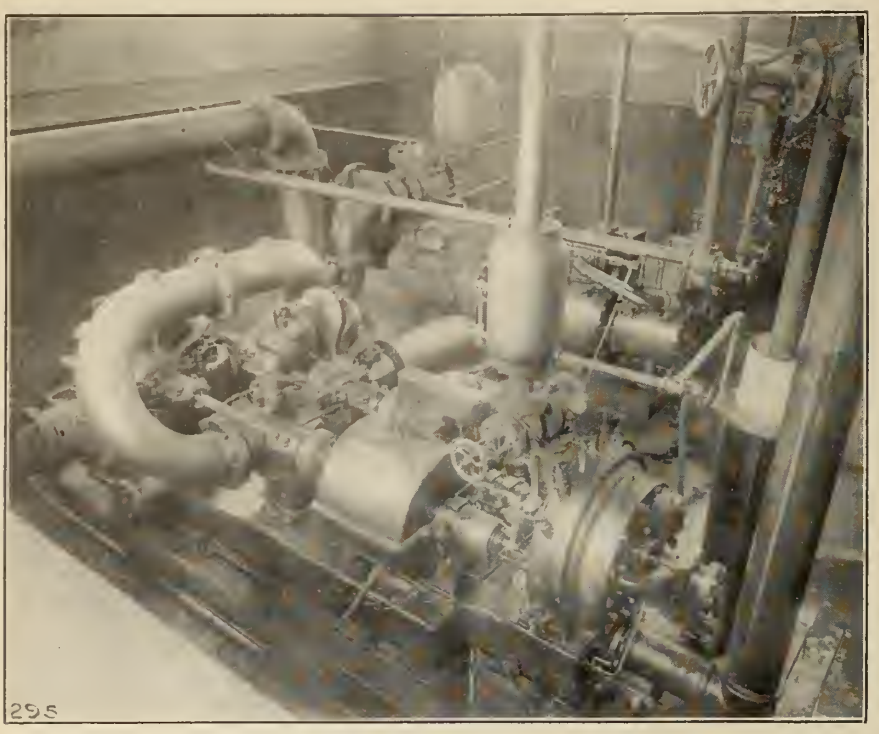

Fig. 3—De Laval Pump Installed at Waterloo, Ontario.

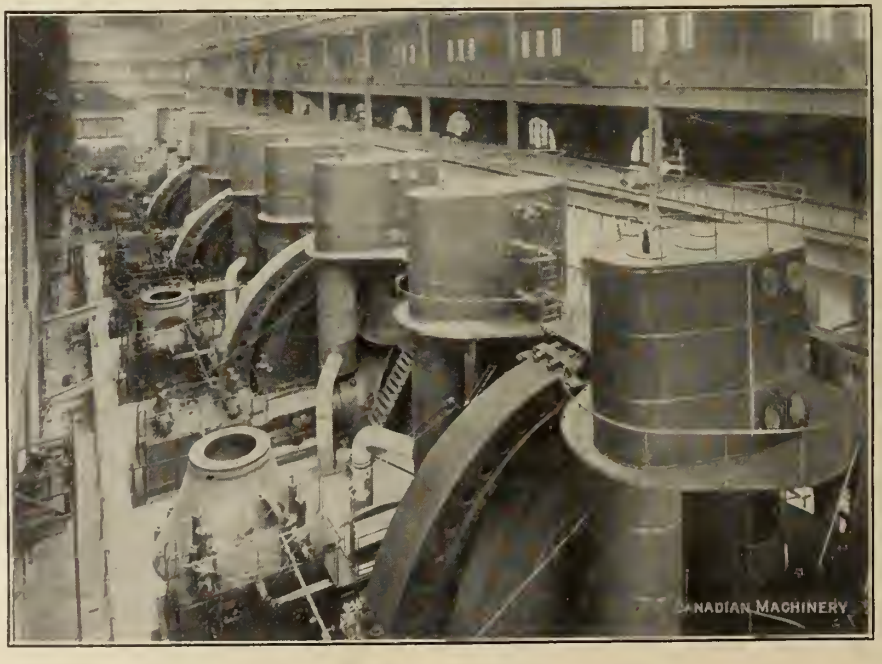
Vacuum	26.02 lbs. (actual.)
Temp. Injection Water	42 36 deg.
" R.H. Discharge	74.05 deg.
" L.H. "	77.38 deg.
Barometer	30.50 lbs.
Water per hour	89.906 lbs.
Drips per hour	512 lbs.
Leakage per hour (boiler)	1.470 lbs.
Boiler Level Correction	60 lbs.
Net Water per hour	87.864 lbs.
Quality of Steam	100.28
Dry Steam per hour	88.110 lbs.
Dry Steam per K.W.H	17.34 lbs.
Dry Steam per I.H.P.	11.96 lbs.

The final results allow for boiler leakage, which was determined by a separate test of 24 hours duration. The steam was very slightly superheated during the test, as being easier to make allowance for than wet steam, and a correction was made to reduce the superheated steam to equivalent dry saturated steam.

The vacuum was carried at 26.02 inches, or as near the contract requirement as possible, but the barometer stood at 30.50 inches. The vacuum was, therefore, equivalent to only 25.52 inches referred to 30 in. barometer; no correction was made, however, as none was provided for in the contract. Other tests at varying vacua show that if the vacuum had been carried enough higher to correspond to 26 in. vacuum when referred to 30 in. barometer, the steam consumption would have been about 0.09 lbs. better, or 11.87 lbs. per I.H.P. hour instead of the official figure of 11.96 lbs.

The tests were under the supervision of Frank N. Waterman, who acted as referee. The following represented their several companies: Interborough Rapid Transit Co., H. G. Scott, superintendent motive power; J. Van Vleck, mechanical engineer; H. W. Butler, principal assistant engineer; Thomas Allsop, mechanical engineer, 59th Street Power Station; C. W. Ricker, electrical superintendent; G. F. Chellis, instrument man; W. L. Seabrooke and W. S. Finlay, assistant engineers.

Allis-Chalmers Co.—A. H. Mattice, chief engineer; Samuel Moore, district superintendent of erection; T. T. Hubbard, engineer test; J. W. Lord, sales representative; C. A. Hoppen and C. J. Larsen, construction department; A. F. Rolf and F. Buch, electrical representatives.



Allis-Chalmers Engines on which test was made.

Doing Things.

Proprietor of Big Iron Works—If I understand you correctly, you wish to place an order for armor plate that no cannon shot can pierce. We are turning out that kind of thing every day—

Agent of Foreign Government—No; you misunderstand. I wish to know if you can manufacture a cannon that can pierce any armor plate?

Proprietor—Certainly, sir. We are doing that kind of thing every day, too. —Answers.

Gratifying Ambition.

Men have two kinds of ambition—one for dollar-making, the other for life-making. Some turn all their ability, education, health, and energy toward the first of these—dollar-making—and call the result success. Others turn them toward the second—into character, usefulness, helpfulness — life-making — and the world sometimes calls them failures; but history calls them successes. No price is too great to pay for an untarnished name.—Success Magazine.

PERSONAL MENTION

Thomas J. Drummond.

MR. THOMAS J. DRUMMOND, who was recently elected by acclamation to the position of second vice-president of the Montreal Board of Trade, is one of the most remarkable business men in the country. Though by no means one who would court publicity his intimate connection with the upbuilding of the Canadian iron and steel industry during the past few years has persistently brought him the public notice. Especially as vice-president of the Lake Superior Corporation he has won great admiration for the plucky fight by which he and his associates have lifted a defunct concern to the level of a good business proposition, and have breathed life into a city where trade was almost at a standstill.

Mr. Drummond's business interests are many and all of them are closely linked with the country's growth and prosperity. He is a partner in the firm of Drummond, McCall & Co., is president of the Montreal Pipe Foundry Co., president of the Londonderry Iron & Mining Co., vice-president of the Canadian Iron & Foundry Co., vice-president of the Lake Superior Corporation, director of the Montreal Water & Power Co., director of the Imperial Life Assurance Co., and secretary of the Canada Iron Furnace Co. He is a member of the executive of the Montreal branch Canadian Manufacturers' Association, and has many other business interests of a less public nature

Thomas J. Drummond,
Elected Second Vice-President Montreal Board of Trade

New General Manager.

IT is officially announced Mr. James A. Milne has accepted the position of general manager of Allis-Chalmers-Bullock, Limited, Montreal. Mr. Milne is a native of Canada, having been born at Waterdown, Ont., in 1872, and is one of the many Canadians who have made their mark in the United States.

RETURNED
APR 10 1906

After completing a public school and collegiate course he began his business career at Toronto in 1888. During the ensuing four years he was with Robert Simpson & Co. and Wyld, Grasett & Darling, of that place, but in 1892 he removed to Chicago, entering the employ of Carson, Pirie, Scott & Company. Subsequently he worked for Reid, Murdock & Co. and the Chicago Packing & Provision Co.—for the latter as chief accountant. Then he became associated with Jones, Caesar & Company, chartered accountants, of Chicago and New York, and it was this connection which brought him into touch with the Allis-Chalmers Company. In August, 1901, he entered their employ as chief cost clerk, and one month later was appointed acting comptroller, being formally elected to that position at the meeting of the board of directors in May 1902. Since the early part of last Autumn Mr. Milne has been one of the directors of Allis-Chalmers-Bullock, Limited, and the fact that he still retains Canadian citizenship, and is deeply attached to his early associations, has been an important factor in influencing him to heed a recall to the Dominion.

J. A. Milne,
General Manager Allis-Chalmers-Bullock.

A New Profession.

ONE of Canada's greatest needs for its industrial progress is the work of technical men who combine their technical knowledge with the sound common sense and an appreciation of the conditions of the matter on hand. One who understands Canada's conditions and needs as well as possessing the technical knowledge and experience, is therefore especially fitted for our needs now.

J. A. DeCew,
Chemical Engineer.

For this reason it is gratifying to announce the establishment in our midst of a member of the chemical engineering profession in the person of Mr. J. A. DeCew.

If Mr. DeCew is somewhat of a pioneer in his chosen work, it is natural, as he comes from the pioneer stock of Western Ontario. He is a graduate of Toronto University, in analytical and applied chemistry, and later spent a year there in research work on cellulose products. Besides his thorough technical training, Mr. DeCew has had wide experience in engineering, in connection with lumbering interests in Oregon, Washington and British Columbia, and later, in industrial chemistry as chief chemist of the Canada Paper Co.'s mills at Windsor Mills.

Mr. DeCew has attained the foremost rank in his profession, being a member of the Society of Chemical Industry, the International Society of Paper Mill Chemists, the American Society for Testing Materials, and the International Society for Testing Materials.

Mr. J. J. Sophus, of McLean & Sophus, Montreal, spent a couple of weeks in February extending the firm's business in Toronto and Hamilton, where he met with a liberal response from the trade in placing different lines for which McLean & Sophus are exclusive Canadian agents.

CANADIAN MACHINERY
and Manufacturing News

A monthly newspaper devoted to machinery and manufacturing interests, mechanical and electrical trades, technical progress, construction and improvement, and to all users of power developed from steam, gas, electricity, compressed air and water in Canada.

ADVERTISING TOWNS AND CITIES.

RECENTLY some Canadian cities were given a proposition regarding advertising their virtues as manufacturing centres in a set of United States magazines and indications point towards a decided step in this direction. Reference has already been made in these columns to the value of publicity on the part of Canadian towns and cities. As matters stand at present the larger cities are enticing the cream of the manufacturing establishments that are being started in this country. According to the report of the Illinois Manufacturing Association 132 of the leading concerns of the United States have been forced to establish manufacturing branches in Canada. The value of these is estimated at $50,000,000. These are figures that should make public spirited citizens of every town and village pause a moment for reflection. Had the advantages of different centres been known by the firms mentioned many of the locations might have been changed. This is a vital moment to the smaller towns where their only hope of growth is in attracting live manufacturing concerns. The metal working industries alone are not sufficient. Industries must be attracted where female employment is given as well as to skilled mechanics. If the towns showed some of the enterprise as corporations that individual members of its business communities show they would not hesitate a moment in circulating far and near the advantages they can offer to induce manufacturers small and large to commence operations within their community. This should not be merely a passing thought but an inborn conviction with the council of every town. Publicity in the papers that circulate from one end of the country to the other is what is needed, and it is hoped that the smaller towns will become alive to the possibilities in this direction, and have the satisfaction of expanding to the greatest possible extent.

Advertise your home town. Some towns are doing this at present with beneficial results. Other places stand by in silence and wonder why they do not receive inquiries from prospective manufacturers as they see one important industry after another locating elsewhere. Get busy. Let the outside world know what you have to offer and note the result. This is the growing time and there is no time like the present.

FACTORS TOWARD SUCCESS.

IT is hard to classify and to give due credit to the various factors which contribute to success in any business. One man emphasizes the necessity of aggressiveness in the sales department—enterprise in making sales and firmness in holding out for a definite price. Another man lays particular stress on the necessity of constant care over manufacturing cost—to the end of producing better goods than one's competitor at equal if not lower cost.

Both men may win success, yet if the general experience of successful men were taken it would demonstrate beyond question that both aggressiveness in selling and economy of production are essential factors to the building up of a large business.

In view of this the manufacturer, whose inclination is toward the mechanical end of his business, should never lose sight of the necessity of enterprise in the sale of his products.

To this end he should use every effective factor which will make his selling force more profitable.

One factor which should never be lost sight of is the necessity of keeping one's name before the buyers he desires to reach. How can this be done most economically?

To answer this entails a study of one's business and of the various mediums through which one could keep his name before the buyers he wants to reach.

For the manufacturer or merchant who has to sell such lines as soaps, pianos, etc., to the average householder, the daily paper, the illustrated weekly, or the popular monthly, is the natural, the most efficient, medium; on the other hand, the manufacturer of machinery, of power equipment, of manufacturers' supplies,

or any such lines, will find most effective and consequently most economical a medium going directly to the owners or superintendents of manufacturing plants—to those who buy the goods he handles.

MODEL EMPLOYES' CLUBS.

SOME of the large manufacturers in the United States have organized clubs, known by the name of the firm, and operated to contribute to the comfort, social intercourse and efficiency of the employes. Every firm employing thirty men, or over, should have such a club, its scope, of course, depending upon the number of men in the establishment. In a place where a large number of men are employed it might provide a dining room where meals would be furnished at cost, as well as rooms for recreation and fellowship. If the number be small club rooms open every night could be secured at trifling individual expense. Here the men might meet and exchange ideas and arrange for a monthly or fortnightly talk by the heads of some of the departments, to the benefit of all concerned. The men would thus become more intelligent, better acquainted with those in authority over them, and an esprit de corps established that may not now exist. The latent possibilities of this idea are great. Every employer of labor should give it some serious thought.

With any and all interested in the formation of such a club we are glad to co-operate and offer suggestions in the shape of a constitution and by-laws for such an organization.

CENTRAL POWER STATIONS AT MINES.

EDISON has made many prophecies, most of which he has been himself mainly instrumental in fulfilling. One of his more recent glimpses into the future is to the effect that before long enormous central stations for the generation of electricity will be situated at the coal mines, and the power delivered by wire at low cost to manufacturing plants, instead of by railroad.

This idea is already under consideration with every prospect of its being carried out at Amherst, N.S., by the management of the Maritime Coal & Railway Company, whose mine is eight miles from the town. Amherst is the industrial centre of the Maritime Provinces, and cheap electric power should prove a further boon. It is proposed to establish at the coal mines a central power station and generate electricity on a large scale. At a recent meeting of the Board of Trade of Amherst, N. Curry, president of the Rhodes, Curry Co.; D. W. Robb, president of the Robb Engineering Co.; H. L. Hewson, president of the Hewson Woolen Mills, and other prominent gentlemen, expressed favorable opinions to the scheme of thus supplying power. The right to enter the town with a pole line has already been granted, so that there is every assurance of the successful operation of the plan within the next few months.

INSTAL THE LATEST MACHINERY

WHEN a manufacturer attempts to run his plant with antiquated machines and apparatus he places himself on a footing with the farmer plowing by means of oxen and sowing and reaping by hand, as one hopelessly out of the running in competition with the up-to-date rival. A striking example of this has taken place in the woolen trade in Canada during the past few years. The directors of different of these plants were more anxious for present dividends than in adopting the latest ideas. Everybody knows the result. Many of the mills were shut down at a total loss, unable to compete with the British manufacturers in the same line who had been throwing on the scrap heap thousands of dollars' worth of machines every year, to make room for the latest and best.

The moral is obvious.

It cannot be too strongly impressed on the manufacturers to-day to instal the most efficient and up-to-date machinery the market affords, as the additional outlay will return to him many fold through the channels of happier and better workmen, increased output, higher prices, satisfied customers and more of them.

TENDENCY IN ENGINEERING PRACTICE.

ONE is constantly reminded of the fact that modern conditions have created a new era in engineering practice in connection with prime movers. Small units are giving way to large, slow speeds have been increased to high, steam pressures have doubled and trebled, voltages have risen from one or two thousand to sixty thousand and higher, and transmission lines lengthened from a few miles to many. People wonder when the limit will be reached, when will that stage have been gained at which power units will be made no larger, speeds no greater, pressures incapable of increase, and potentials beyond the power of insulation. Meanwhile the cycle continues and the movement is unabated in the direction of units, greater and greater, and potentials, pressures and velocities, higher and higher. Engineers and designers are busy creating monsters, only to find that they command attention for but a few months at best, when they are superseded by others of still greater capacity. It takes some nerve to design a machine with a peripheral speed of four miles a minute, and no small calculation to get proper shapes that stresses may be uniformly distributed and minimized at this speed. But who will say that the limit has been reached?

A prominent electrical engineer predicts that the next few years will see units of 25,000 k.w., while at present we are marveling at leviathans of half that capacity. In spite of this there must come before long a halt, for sooner or later we will arrive at the point, a mean between size or speed or pressure and economy to build, operate and maintain.

Modern Tendency in Boiler Practice

By H. W. Weller, A.M.I.C.E. and M.AM. Inst. E.E.

RETURNED
MAY 2 1906

Early Development.

FROM 130 B.C., when Hero of Alexandria brought out his "Aetoipile," or rotating steam engine, to the present day is a far cry, but the fact that the latest development in steam power, namely the turbine of to-day, depends upon the application of the same principle as that of Hero's ancient prime mover, proves again that "there is nothing new under the sun." It is not within the scope of the following remarks to refer to the various inventors from the above commencement to the time in 1712 when Thomas Newcomen accidentally discovered the condensation of steam by a jet of cold water, and the various improvements made by John Smeaton and James Watt in 1760-1770, and the marked advances by Boulton and Watt a few years later.

Boiler Installation, Canada Car Co., Montreal.

In all these earlier experiments and achievements the steam pressure was very low, probably never exceeding 20 lbs., the inventors depending largely on the vacuum produced by the cold water injected into the cylinder to condense the steam. Up to 1781 all the steam engines were single acting and only used for pumping purposes, but in that year Watt obtained a patent for a double acting engine, which was the first important step in the production of a "continuous motion" engine.

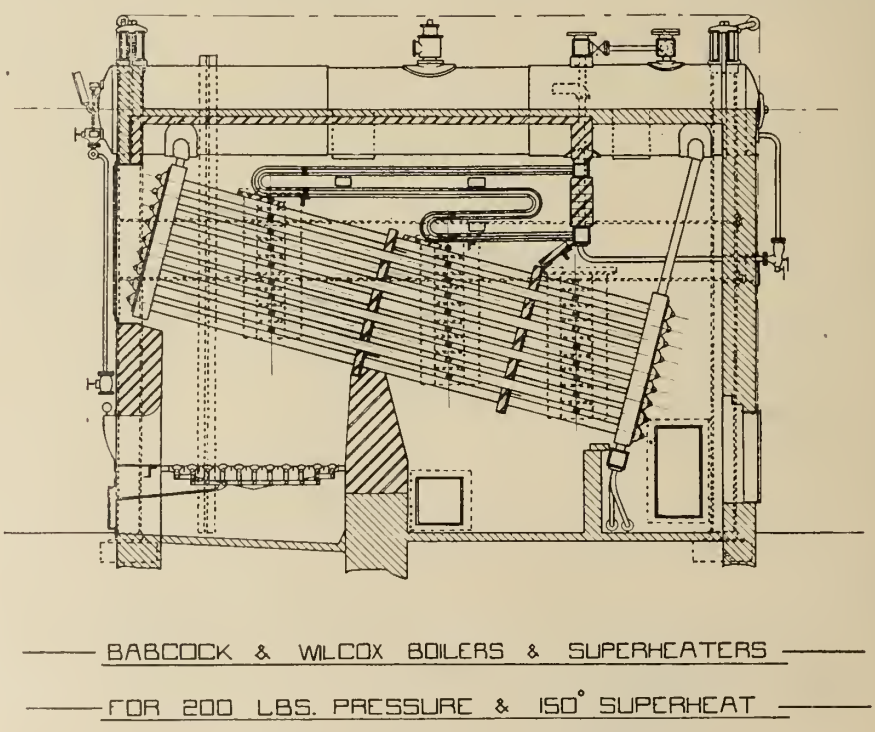
Onward Progress.

It is not intended here to follow the various advances made in the development of the steam engine, which would no doubt be very interesting and instructive to many readers, but rather to point out the steady increase of steam pressures from the days of Watt until the present time. The march of progress is always onward, and the pressure of 20 lbs. in the beginning of the nineteenth century caused more wonderment than 250 lbs. does at the present time. To-day with our modern triple expansion engines and steam turbines, 250 lbs. and 150 degrees of super-heat is not at all uncommon, and if we would develop our steam power to-day at the least possible cost in order to compete with water power and gas engines, we must have engines and boilers of the highest efficiency, and to obtain that efficiency we must look for it in high pressures and super-heated steam. It is true that our engines must be stronger and better made, and that the design, material and workmanship of our boilers must be, like Caesar's wife, "above suspicion." Furthermore, our engineers and firemen must be better educated and more intelligent men and ready to carefully consider the various advances made from time to time and not prone to condemn any new idea because they do not understand it, or say "what was good enough for their father is good enough for them."

In the boiler, the progress made has not been rapid. Men have been inclined to consider that anything called a boiler which an inspector would pass, was good enough for them, and looked upon the various troubles and repairs as necessary evils, and that an occasional explosion was only a part of the business, and that anyone who was unfitted by lack of intelligence for a more responsible position was good enough to shovel coal into the furnace—and that so much coal just had to be burned anyway.

To-day manufacturers are beginning to see with different eyes, and are tending to give more of the intelligent care they use in other departments of their business to the boiler room.

The old egg-ended boilers, internally fired boilers, and later the horizontal tubular or fire tube boilers, have been successively used, and each has filled its place in the onward march, but as the pressures have kept increasing they have reached the limit of their safe commercial usefulness, and to-day practical, up-



Boiler being Installed in Incinerator Plant, Westmount.

to-date engineers realize that if safety and economy are to be realized they must look elsewhere for the steam generator of the future. Some fifty years ago inventors started to build pipe boilers in which the water was contained inside the pipes, and many arrangements were tried, one after another proving failures. But the water tube boiler was the rational outcome of the desire for safe and economical steam generation, and to-day we probably have over 20,000,000 horse-power of one kind and another in use. Of course inventors have been prolific in ideas, and many of the types brought out have been abandoned owing to the lack of the fundamental principles underlying the production of a successful boiler, and this has brought abuse and discredit upon all boilers of this type. It may, therefore, be interesting to some Canadian Machinery readers to have put before them a few of the main points which must not be lost sight of, if we would have a successful and satisfactory boiler. These rules were laid down many years ago by Mr. George Babcock, one of the pioneers in this line of engineering, and his judgment has been upheld by all the best engineers of the last twenty-five years.

Boiler Requirements.

The essentials of a perfect steam boiler may be given briefly as follows :

1. A large factor of safety.
2. Steam and water capacity sufficient to care for sudden fluctuations of load.
3. A proper arrangement of heating surface to thoroughly absorb the heat of the gases.
4. The absence of any stayed surfaces.
5. Straight tubes so that they can be cleaned easily and so that you can see through them and know that they are clean.
6. Sectional construction to insure safety and ease of repair.
7. Wrought steel construction throughout.
8. Ample surface to disengage the steam easily so as to avoid priming or a fluctuating water level.
9. Expansion and contraction properly provided for.
10. And last, but not least, a perfect and positive circulation of the water.

Added to the above it is imperative on the score of economy that the soot can be easily removed from the heating surface, while the boiler is in operation, preferably by means of air or steam jets.

To-day we have several plants in Canada where the engineers have recognized the value of the higher pressures, two of which are illustrated.

The Canada Car Co. have installed water tube boilers good for a continuous working pressure of 200 lbs. and fitted with steam super-heaters capable of imparting 150 degrees F. of super-heat to the steam.

Recent Installations.

The Corporation of Westmount for their new destructor and electric light plant have done the same. Also we may mention the Central Electric Co., the Northern Electric Co. and the Locomotive & Machine Co., while the C.P.R. at their Angus shops have a large boiler built for 300 lbs. working pressure and 150 degrees F. of super-heat.

It may not be out of place to point out that all the most recent and up-to-date battleships and cruisers of the British and American navies have been equipped with the straight tube type of water tube boilers. There is a saving of half the weight and the ability to carry 250 lbs. working pressure indefinitely, and you have the most powerful reasons for the use of the water tube boiler for marine work. The Dominion ice-breaker "Montcalm," which has been doing such good work on the lower St. Lawrence for the past twelve months, is equipped with 4,500 horse-power of water tube boilers of the Babcock & Wilcox make, and H.M.S. Dominion, which brought home the body of the late Minister of Marine, is fitted with 18,000 horse-power of water tube boilers of the same make.

Advantages of Superheat.

In conclusion it might be well to further emphasize the advantages of moderate super-heat of say 100 to 150 degrees F.

In most plants, if properly piped and protected, this amount of super-heat will not only avoid condensation in the steam mains, but will practically eliminate the condensation losses in the high pressure cylinders of the engine and this alone will show an actual saving varying from 10 to 25 per cent. according to the class of engine and its condition. This, coupled to the saving effected by the use of high pressure steam, and boilers that can be cleaned and kept up to their efficiency while at work, is of such importance in considering the cost of operation that no thinking user of steam can afford to disregard it.

In a series of tests made on the steamer J. C. Wallace last Summer on the Great Lakes, by Commander White of the United States navy, the first two were made with super-heated steam only 82 and 88 degrees F. respectively, the dry coal burned per I.H.P. was 1.464 and 1.598 lb. per hour and with saturated steam 1.747 and 1.713 lb. per hour, the engine being a high class triple expansion. With a less economical engine the relative saving would be much greater.

VALUING COALS BY TEST AND ANALYSIS.

By J. A. DeCew, B.A.Sc., Chemical Engineer.

THE statement we sometimes hear that "coal is coal," has about the same significance as if the person had said "wood is wood;" and this, to an inhabitant of America, with its many and beautiful varieties and species, is a sly bit of humor. In the former case, however, the evidence to the contrary is not so apparent, and it is not so generally recognized that a close relationship exists between the economy of the steam boiler and the quality and character of the coal it consumes.

The economical coal for one boiler plant is not necessarily the most economical for another, on account of such difference in conditions as, kind of furnace, area of grate surface, draft available, etc. It follows, therefore, that the only way to determine the coal having the character most suitable for any steam boiler, is to make a practical test under the ordinary running conditions of the plant.

The results of this trial, however, are limited in their value and application, unless we know something of the characteristics and qualities of the material under consideration. These factors are determined from an approximate analysis and determination of the calorific value of coal.

Experience may be thus recorded in a terminology, that is, definite, descriptive and specific, from which is finally evolved a knowledge of the exact specification of the material which will be most suitable for certain conditions and circumstances.

Let us now note more specifically some of the variable factors upon which depends the cost of steam production.

1. We have the relative cost per ton of the different kinds delivered at the boiler.
2. The relative total heating value per pound or per ton.
3. The relative percentage of heating value which may be utilized in the boiler.
4. The maximum capacity or horse-power that can be developed by the boiler with different coals.
5. The relative smokelessness when used in the particular boilers and furnaces under consideration.

Now, with proper experimental work, using coals whose characteristics are known in terms of their proximate analysis, it is possible to eliminate the last four variables by ascertaining the proportion of constituents, such as moisture, ash, volatile and fixed carbon, which produce the best results in actual trial.

Let us now assume that this stage has been reached and that the purchaser knows the characteristics of the material he wants. Then, all we have left to consider is the cost per ton and the total heating value of the material.

Thus follows the simple proposition that, other things being equal, the value of a coal varies directly with the calorific value. For instance, if the consumer gets 13,000 B.T.U. per pound of coal at one time, and 12,000 at another, he is not paying the same price for his coal. It is possible to obtain a fair idea of the value of a coal from the proximate analysis alone, thus:

The amount of volatile matter expressed as a percentage of the combustible, classifies the coal as anthracite, semi-bituminous or bituminous.

The moisture in a bituminous coal is an important guide as to its character.

The quantity of ash is a criterion of value because it interferes with evaporation power by reducing the amount of combustible and also by enclosing particles of carbon, which retards excess of air and prevents complete combustion.

The amount of sulphur in a coal is also an indication of the value of coal, for high sulphur is generally found in a coal that clinkers badly, and from which it is hard to obtain the rated capacity of the boiler.

Therefore, why should we ignore these important factors in the choice and use of a material which is the basis of nearly all industry Even if chemical methods have occasionally produced unsatisfactory results when they lacked the practical knowledge of the man on the spot, yet, why should the man in charge and with the responsibility on his shoulders, limit and retard his efficiency by ignoring the assistance and failing to utilize the methods of science that are now at his disposal, the sole aim of which is to assist in the production of economies and profits?

Recent Engine and Boiler Patents.

SOME of the latest inventions dealing with patents, with their object the improvement of steam engines and boilers are presented herewith, for which Canadian Machinery acknowledges the courtesy of Fetherstonhaugh & Co., patent solicitors, Toronto and Montreal.

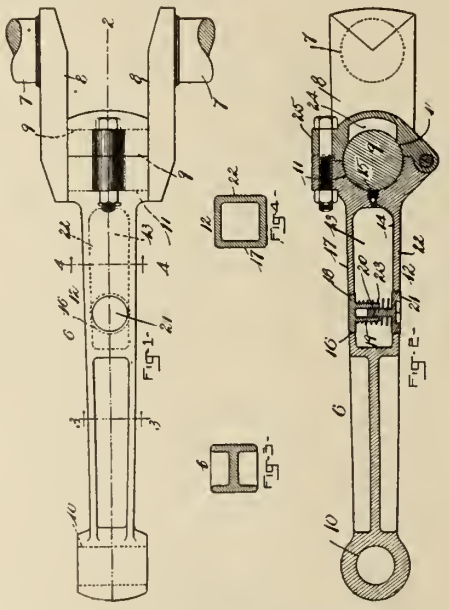
Connecting Rod for Engines.

This invention is particularly adapted to connecting rods for high speed gasoline engines. The object of the invention is to provide a connecting rod which comprises in its construction a convenient means for lubricating the crank pin of the crank shaft to which one end of said connecting rod is attached, and to this end the connecting rod is provided with a chamber adapted to contain lubricating material in solid form, such as grease, and connected by an outlet passage at one end thereof with the bearing formed in the adjacent end of said connecting rod and encircling the crank pin, and also provided with an inlet orifice constructed to enable the grease to be readily inserted in said chamber, and after being inserted means to lock the orifice through which it is inserted, so that the same cannot leak out of the chamber.

Referring to the drawings, Fig. 1 is a side elevation of a connecting rod constructed in accordance with the invention, showing the same connected to the crank pin of a crank shaft. Fig. 2 is a section, partly in elevation, taken on line 2 2 of Fig. 1. Fig. 3 is a transverse section of the connecting rod, taken on line 3 3 of Fig. 1. Fig. 4 is a transverse section of the connecting rod, taken on line 4 4 of Fig 1.

Compound Engine.

In this invention the object sought is to provide a construction of distributing mechanism for two or more cylinders in which the steam after being used in one cylinder will be returned to the valve in its passage to a second cylinder, and will thereby be subjected to a reheating action.



Connecting Rod for Engines.

In the accompanying drawings, which illustrate several embodiments of this invention, Fig. 1 is a longitudinal sectional view of a two-cylinder engine, illustrating one embodiment of the invention. Fig. 2 is a cross-sectional view of the same. Fig. 3 is a longitudinal sectional view of a three-cylinder engine embodying the invention. Fig. 4 is a cross-sectional view of the same.

Steam Boiler Superheater.

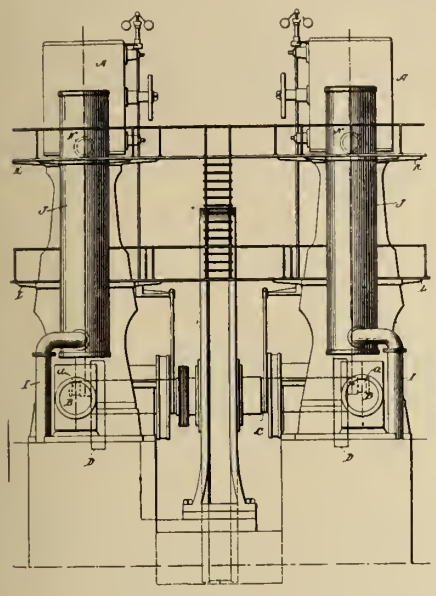
This invention relates to superheaters of the general class or type in which the superheater pipes are located in fire tubes of a steam boiler; and its object is to provide a superheating appliance of such type in which the saturated steam shall he subjected to the heat of the gases passing through the superheating tubes while traversing in reverse direction to said gases and after having been raised thereby to the maximum temperature shall be protected from loss of heat by transfer thereof to the succeeding saturated steam during its return traverse toward the steam delivery connection.

Fig. 2 shows a front view, partly in section, of slightly more than one-half of the T-head with one of the headers detached and indicated in broken lines; Fig. 3, a horizontal central section, on an enlarged scale, through one of the headers and a superheating fire tube and through the superheater pipes located in said tube; Fig. 4, a transverse section on the line a a of Fig. 3; and Figs. 5 and 6 similar sections showing the appli-

cation of a larger number of superheater pipes in each superheating tube.

Steam Engine.

This is an important invention and has been assigned to the Allis-Chalmers Co.,



Reynolds' Steam Engine.

of Chicago. It pertains to steam engines, and consists in novel combination of vertical and horizontal engines, simple or compound, and in the various features connected with the union of such vertical and horizontal engines. Among the objects sought are uniformity of turning effect, static balance of the engine in all positions, or at every point of the stroke,

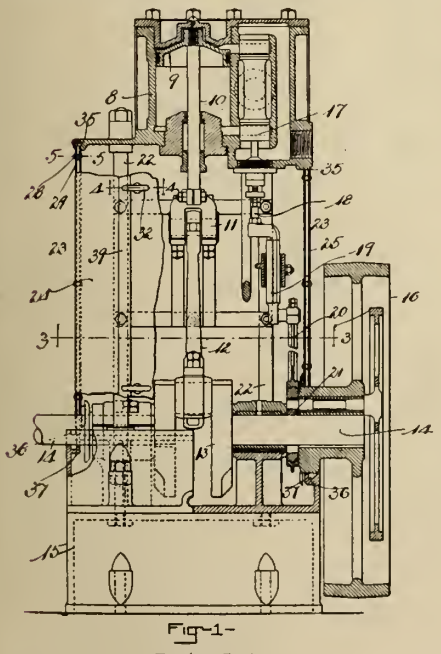


Fig-1-

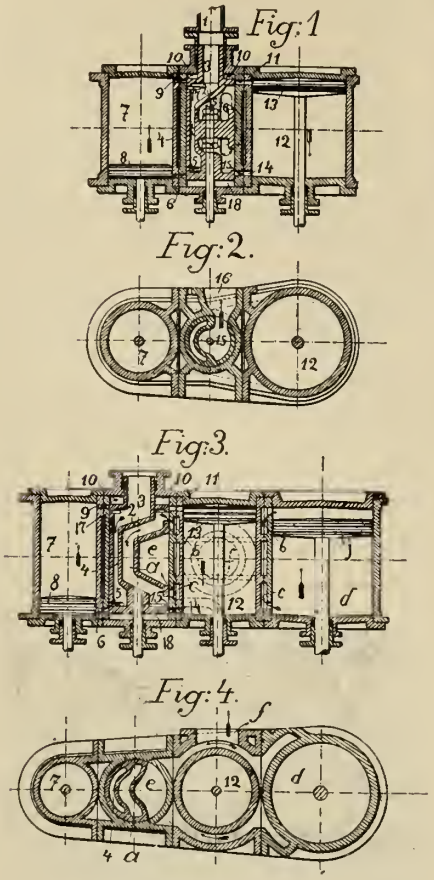
Engine Casing.

facility of coupling or connecting the engine or engines to the machinery to be driven, compact and convenient arrangement of a series of such combined engines in line with each other and proper distribution of stresses.

The view given is a front or face elevation of a double compound engine constructed in accordance with the present improvements, but the application is much broader than can be shown by one view. The arrangement shown produces an extremely compact and rigid structure, and permits direct connection of both engines with the shaft. It permits the disconnecting of any one cylinder of the four in case of accident or the disconnection of one unit to allow the remaining unit to be worked at best economy when delivering half the power of the

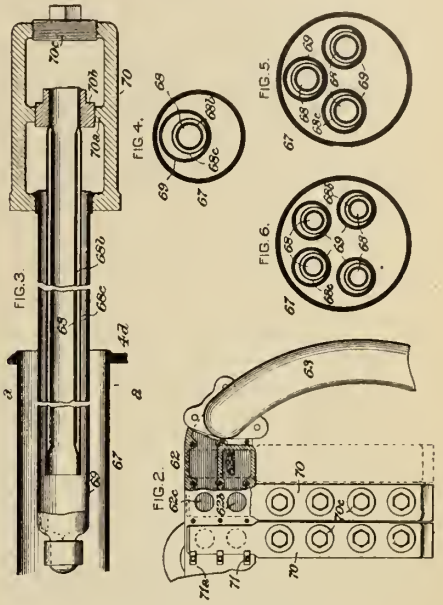


Compound Engine.

generator. It allows the concentration of great power in one shaft with but moderate power in each cylinder, which becomes very important in powers of 6,000 horse-power and upward. There are only two bearings in the shaft, which makes it much easier to keep the engines in alignment, as with the great weight of generator and fly wheel required, a certain amount of deflection in the shaft is unavoidable, which makes it extremely difficult to keep the bearings in good shape when there are more than two bearings. Finally, there are no double-throw cranks, which are always a source of expense and weakness.

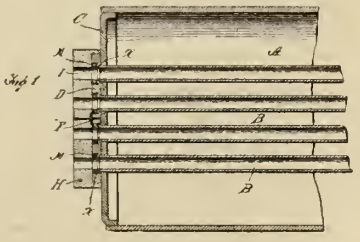
Steam Boiler.

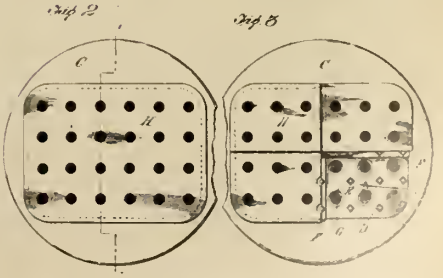
An improvement to steam boilers of the class in which fire tubes will pass hori-



Steam Boiler Superheater

zontally through the boiler, connecting at their ends to the boiler head, and the principal object is to provide a strong and durable connection between the tubes and boiler heads to protect these joints and to prevent leakage. The ends of the fire tubes in this boiler are connected to the boiler heads in the usual way, and to the rear head, next the fire box, is attached a protecting plate of improved construction. This plate is preferably





Improved Steam Boiler.

made in four sections, so that it may be more easily applied to the boiler and in order that only one section need be taken down when repairing some defective

flues. Each section of the plate is formed with holes registering with the tubes and with annular flanges around the holes adapted to register with and be calked to the annular beaded ends of the tubes outside the tube sheet. The plate is bolted to the tube sheet and may, if desired, be calked all around its edge. Preferably the plate is made in four sections, as above stated, and the joints of the sections are covered with metallic strips, which are also bolted to the tube-sheet and are preferably calked to the plates. As an additional protection, the plate is covered with a protecting wall. The wall has holes registering with the holes in the plate and the tube. The accompanying drawing, Fig. 1, shows a vertical section of a portion of a steam boiler with this improvement applied, the section being taken on a line I I of Fig. 1. Fig. 2 is an end elevation, and Fig. 3 shows an end elevation with one section of the protecting wall removed.

Engine Casing.

The inventor of this has for his object an improvement in the casing of engines whereby the oil which is attached from moving parts is confined within the casing and said moving parts are enclosed thereby in such a manner that the exterior of the engine is kept free from oil and dirt. Fig. 1 shows a side elevation, partly broken away and in section, of a steam engine with the improved casing attached.

Steel Smoke Stacks for Mills

By F. C. Douglas Wilkes, B.Sc.

(Continued from last issue.)

The stack base is then hoisted into place and securely fastened to the brickwork by its foundation bolts. Care should be taken that the base plate is perfectly square and plumb. If this is not carefully attended to the result will be that the stack is considerably out of plumb at the top. The first sheet is then hoisted into place and is temporarily though securely fastened by angles made out of bar iron ¾ by 3-inch in size. The second sheet is then hoisted into place and the two sheets are then drawn together by bolts placed temporarily through the rivet holes. The cage is not used on the first course and to facilitate the rivetting of the seams a temporary scaffolding is erected from the roof of the building or from the ground if the brickwork is separate from the building. Care should be taken that the first course is perfectly square and plumb for the same reasons mentioned above. The platform is now raised to within about 12 inches from the top of the first course and the crane support takes the place of the platform and rests on the two tie pieces from which the platform has just been taken. This crane support fits the circumference of the stack loosely but is prevented from turning by the uprights which have been added to the scaffolding to support the platform in its new position. The first sheet of the second course is now hoisted into place and fastened by bolts through the rivet holes as before. The bolts in the centre of the sheet are put into place by using a long pair of blacksmith's tongs or similar appliance. The second sheet is now put into place and the cage comes into use for the first time. This hangs from the top and rests against the last course erected which has been made perfectly stable by the rivets. The cage can easily be moved around the stack by virtue of the wheels. The man with the "dolly bar" has his place in the cage, the rivets are heated inside the stack, passed out to him and driven from the inside. To give more room for the swing of the hammers the crane mast can be lowered until it hangs from the platform by its cross piece. While the platform is being raised for the next course the forge, which would be in the way, is lifted into the cage until needed again. When the first sheet of the third course is fastened in its place by its temporary fastenings the cage is hoisted up and hung on that sheet until

III.—Top of Stack, Showing Screen.

the second sheet is in place ready for the rivets. The same procedure takes place until the stack is finished. Figure 4 shows three courses finished with the crane and cage in position. About thirty-five or forty feet up temporary guy wires are fastened to the stack by means of eye bolts through rivet holes left open for that purpose. When the stack is finished and the permanent guy wires are in place the temporary ones are removed by a man let down in a sling and the holes plugged by cold driven rivets. As the scaffolding is raised a ladder is constructed by nailing cross pieces to the uprights. The stack is then painted from the top down by a good quality of special stack paint. Ordinary paint would last about six weeks but a good stack paint will last for years.

Photo No. 3 shows the top of a stack with the screen and screen door in position. The mesh is reinforced by angle irons riveted to it on the inside.

Some stack builders put a band around the bottom of the stack but this is not a good practice as it is impossible to keep the moisture out from between the band and the stack, and this lodging there soon rusts the stack through. Because of the same reason the guy wires should be fastened to the stack with eye bolts with washers on the inside, instead of a band as is sometimes used.

THE SCALE NUISANCE.

ONE method of getting rid of old scale is to boil up and cool down a boiler once or twice with a powerful dose of soda. Mica in natural rock seems to produce a weak texture, and perhaps has that effect in the case of scale. I would like to suggest to station engineers who have scaled boilers to scrap that they should try the effect of a 10 or 20 per cent. solution of hydrochloric acid in removing scale. Probably the acid would leave the plates alone so long as any scale remained to be dissolved. If the acid does not injure an old boiler it might be then trusted in new boilers. Old scale will also come loose in time if treated with softened water. The locomotives on a railway using water from a chalk well have been cleared of scale by changing over to a well in the Tunbridge sandstone.—W. H. Booth (Proc. I.E.E.)

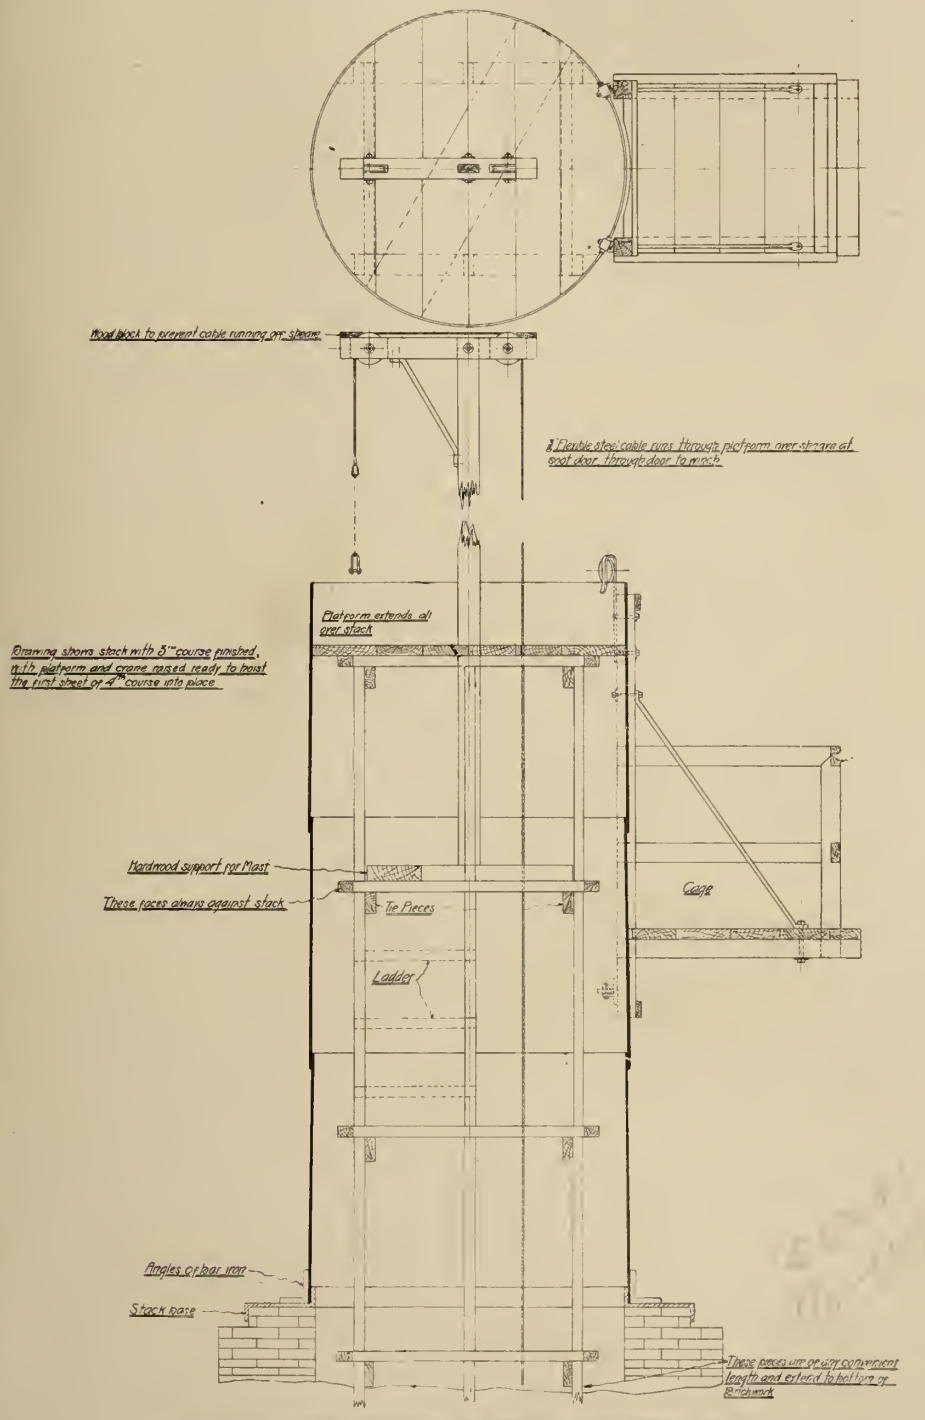
Practical Mechanics

By W. H. Raeburn

Article V. A descriptive discussion of an important subject, simply and clearly stated. Every article of this series should be read and studied by all readers of Canadian Machinery. They are practical and helpful.

CALCULATING SPEEDS OF GEARS AND PULLEYS.

OBJECTS in motion have more or less fascination for every beginner in the study of mechanism and many of our younger readers engaged in the machine trades are anxious to know a little about gearing—both about the arrangements necessary in order to produce desired results in movement and also about the proportions of teeth, sizes of blanks, etc. Our older readers—older in knowledge—must remember that these articles are for the beginner, and we were all beginners once, so that what appears very simple indeed to some is not too elementary for others.



Wood block to prevent cable running off stream
Flexible steel cable runs through platform over stream at foot door, through door to winch
Platform extends all over stack
Draining storm stock with 3rd course finished, with platform and crane raised ready to hoist the first sheet of 4th course into place
Hardwood support for Mast
These pieces always against stack
Tie Pieces
Ladder
Cage
Angles or bar iron
Stack plate
These pieces are of any convenient length and extend to bottom of Brickwork

Fig 1—Method of Erecting Stacks Made of Riveted Steel Plates.

Relative Motion of Gears.

Let us briefly consider the motion of toothed wheels, or gears, as they are generally named.

In Figure 1, (A) and (B) represent two plain circular discs revolving on centres (C) and (D). These discs are in contact at (E), where there is just enough friction between them to produce motion in either one when the other is rotated.

Assume that disc (B) is revolved in the direction indicated by the arrow, then it is clear that (A) will revolve in the opposite direction. We shall now show that the revolutions of these discs in a given time will be in inverse ratio to their diameters.

To take a simple case: Let the diameter of (A) be twice that of (B); the circumferences will be in the same proportion to each other, and the distance, that is, one-third of the circumference of (B), is one-sixth of the circumference of (A), so that without complicating the matter with algebraic expressions we see that (B) will have to revolve twice to produce one revolution of (A). For any other ratio of diameter the same rule holds good, so that we can safely base all calculations for friction or toothed gearing, chain or belt drives on this — the number of revolutions of one wheel multiplied by its diameter equals the number of revolutions of the other wheel multiplied by its diameter. In the case of gears the numbers of teeth are used in place of the diameters, and it need hardly be stated that the numbers of teeth in two wheels are in direct proportion to their circumferences, which again are in direct proportion to their diameters.

We used plain cylindrical discs in our illustration, and in gearing such imaginary discs would correspond to the pitch circles, the points of the teeth being formed above or added to these circles, hence the term addendum, while the body of the disc would be cut away to allow the point of the mating gear to engage, such cutting away being great enough to give clearance. We shall consider the matter of gear teeth more fully at a later date, when the proportions of teeth, sizing of blanks, etc., will be dealt with.

In Figure 2 we have four gears used in transmitting motion and power from shaft (a) to shaft (b), the gears (B) and (C) being idlers used to fill the gap between (A) and (D), thus avoiding the

use of much larger gears on the two shafts.

If gear (A) makes 1 revolution in a given time (B) will make $1 \times \frac{20}{36} = \frac{5}{9}$ rev.; (C) will make $\frac{5}{9} \times \frac{36}{30} = \frac{2}{3}$ rev., and (D) will make $\frac{2}{3} \times \frac{30}{40} = \frac{1}{2}$ rev. in the same time.

Now, we might have omitted finding the speeds of (B) and (C), for that of (D) is the same as if it engaged directly with (A), thus: $1 \times \frac{20}{40} = \frac{1}{2}$ rev.

The arrows indicate the direction of rotation which must be kept in mind when arranging gearing. Although this is frequently called a train of gears, the term is more generally applied to the combination shown in Figure 3, which represents a train of gearing such as is used in the drive of an iron planer.

To Find Speed of Planer Table.

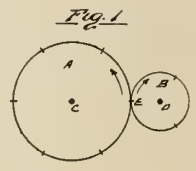
Let it be required to find at what speed the shaft (D) will have to revolve in order to move the table at the rate of 30 feet per minute.

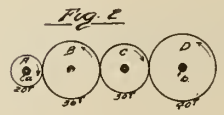
The gear that engages the rack attached to table is, as will be seen, an intermediate or idler so that we may for our present purpose consider the 16-teeth pinion on shaft (A) as gearing directly with the rack. This pinion has a circumference on the pitch circle of $16 \times 2 = 32$ in., and in order that a point on this pitch circle will move at a velocity of 30 feet or 360 in. per minute, the pinion must revolve $\frac{360}{32} = 11.25$ times per minute, thus establishing the speed of shaft (A). (B) will make $\frac{48}{16}$ times the revolutions that A makes, (C) will make $\frac{63}{18}$ times the revolutions that (B) makes, and (D) will make $\frac{64}{20}$ times the revolutions that (C) makes. We need not find the speeds of (B) and (C), but proceed as follows to find that of (D) $= 11.25 \times \frac{48}{16} \times \frac{63}{18} \times \frac{64}{20} = 189$ revolutions.

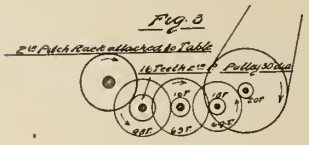
Work Being Done.

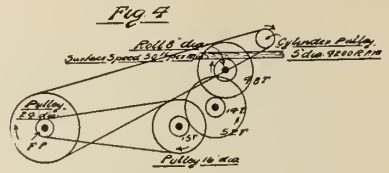
We shall apply the principle of work explained in a previous article to this problem by finding driving force acting at the table when we use a certain size of pulley and width of belt. The pulley being 30 in. diameter, its circumference in feet will be $2.5 \times 3.1416 = 7.854$ feet and as it revolves at the rate of 189 revolutions the velocity of the rim or of the belt will be $189 \times 7.854 = 1484$ feet per minute. Taking the belt as 3 inches wide with a working tension of 55 lbs. per inch of width, we have 165 lbs. for the pull of the belt and $165 \times 1484 = 244.860$ ft. pounds of work done by the belt in a minute.

If there were no loss from friction between the points of application and delivery of the power the work delivered would equal the amount just stated or the pressure exerted on the rack under the table multiplied by 30 ft. $= 244,860$ ft. lbs., so that it is clear that pressure would be $\frac{244860}{30} = 8,162$ pounds. There may be about 10 or 12 per cent. of loss









due to friction of gearing and bearings so that the actual pressure on the rack would be about 7,300 lbs.

The drive of a wood plane affords a good example for our consideration. Such a drive is represented in Figure 4, where the elements of the gearing will be recognized by those having even a slight knowledge of this class of machinery.

To Find Speed and Diameter of Pulley.

We are given the size and speed of the cylinder pulley and wish to find the speed of the countershaft on which is placed a pulley or pulleys of known size to drive the cylinder. We are also given the diameter of feed roll, the number of teeth in the feed drive gears and the diameter of the pulley on the first pinion shaft. From these we are to find the diameter of the pulley (F.P.) on the countershaft.

First we shall find the speed of the countershaft. The cylinder pulley being 5 in. diameter and its speed 4,200 revolutions per minute, we have $5 \times 4200 = 21,000$; this, as we have explained above, must equal the size of the driving pulley multiplied by its speed, so that $24 \times$ rev. of countershaft $= 21,000$; thus the required speed is $\frac{21,000}{24} = 875$ revolutions.

If this speed had been given and the diameter of pulley unknown we would have found the latter as follows: $\frac{5 \times 4200}{875} = 24$; or if both diameter and speed had been given and also the diameter of the cylinder pulley the speed of the latter would have been found thus: $\frac{24 \times 875}{5} = 4200$,

Proceeding to the feed, the circumference of a roll 8 in. diameter is $\frac{8}{12} \times 3.1416 = 2.094$ feet, so that the roll must revolve $\frac{50}{2.094}$ times a minnte in order to feed the board at the rate of 50 feet.

Taking each pair of gears as we did in the case of the iron planer, we have $\frac{50}{2.094} \times \frac{48}{14} \times \frac{52}{15} = 283.7$ revolutions the speed of the 16 in. pulley.

To find the size of the pulley (F.P.) we multiply the diameter of the large pulley by its speed and divide by the speed of the countershaft $\frac{283.7 \times 16}{875} = 5.18$ in.

In practice we would make this pulley $5\frac{1}{4}$ in. diameter, thus allowing a small margin for slippages.

In our next article we shall consider among other things the gearing on a lathe for screw cutting, a matter that should be of interest to many.

A REMEDY FOR TRAVELING MEN.

TRAVELING men, who spend a great deal of time on trains and in hotels, and who get wearied of the ordinary run of newspapers and magazines, will find The Busy Man's Magazine very refreshing. This periodical is unique in the periodical field. It is more than a magazine—it is a score of magazines all in one. Like the composite photograph of a hundred authors, The Busy Man's Magazine is a composite publication of a hundred periodicals. It culls the best from them all and presents it in an appetizing and invigorating form. Every travel-worn commercial man should try this new remedy for the weariness of the road.

Construction and Improvement

General Construction *Contractors' Supplies*

NEW CEMENT BLOCK MACHINE.

A PATENT has just been granted on the cement block machine shown in illustration for the conomic manufacture of this important accessory in building construction. The machine comprises a frame, a pivotally mounted and evenly balanced body, a forming box composed of movable members, carried by the latter; cores adapted to enter the box from the rear and a rack formed on each of these cores. A gear wheel engages this rack while a four-arm crank is pivotted centrally at the rear of the box. There are four adjustable screw rods, connected at one end on the crank and at the other end to each of the four movable box members. A hand operating lever is secured to this crank for the purpose of opening and closing the box members simultaneously. A truck mounted on a track formed on the frame is adapted to receive the contents of the box when the block is formed.

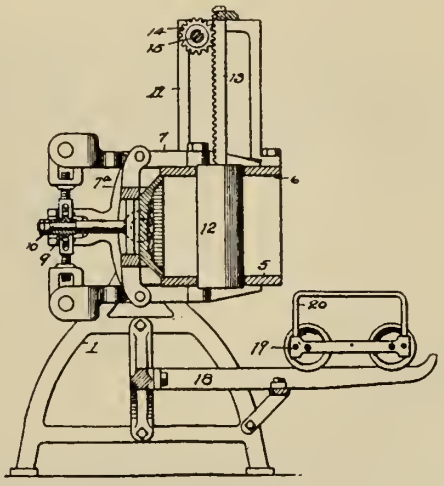
A NEW USE FOR GLASS.

LIKE reinforced concrete, reinforced glass is now more and more employed in buildings. Reinforced glass is made by rolling two sheets of glass between which is placed a metallic grating. The product shows remarkable cohesion and tenacity; and, in case of breaking, the pieces of glass, instead of separating, remain adherent, held by the metallic grating. That is the principal advantage of reinforced glass. By intersecting experiments, recently made, MM. Schlernitzauer and Crocket, of Paris, France, have proved that a plate of reinforced glass, slightly less than a quarter of an inch thick, and a trifle over four feet long by a foot and a half wide, could support a weight of about 1,047 pounds. Under 1,322 pounds it did not break, but was only bent and cracked. Reinforced glass has another important property: a small building, the walls of which are made of reinforced glass, resists a very lively fire lit on the inside; whereas an ordinary window breaks at the first touches of the flame.

Such properties clearly fit reinforced glass for roofing, shop-windows, and glass partitions; but its application to the construction of staircases is particularly successful, for glass staircases allow the easy lighting of the descents into the basements. Their steps are not slippery, and, in case of fire, their superiority over wooden staircases is incontestable.

CONCRETE AND THE STEEL BUSINESS.

WHEN concrete construction was first proposed and thorough experiments had demonstrated that it was a practical, cheap and durable building material, it gave rise to considerable apprehension on the part of steel-makers, who foresaw in its increasing use a possible substitute for steel-construction. They have since discovered, however, that to



Cement Block Machine.

a very large extent the introduction of concrete has increased rather than diminished the demand for steel. It has permitted the construction of an extensive class of structures, including mills, factories and office buildings, at a largely reduced cost compared with old methods, and in supplying the reinforcing materials for these buildings has created a market for a heavy tonnage of steel.

If every building recently constructed of concrete could with equal advantage and expense have been erected of structural steel, the maker of the latter would clearly have sustained a loss through the introduction of the new process. But this is not stating the case fairly. The reduced cost of concrete construction, the ease and promptness in securing materials, and its rapidity in working, have made possible many buildings which otherwise would not have been erected. The record of building in the last few years has been one of unprecedented growth. Every concrete structure requires a considerable amount of steel bars, as well as a goodly quantity of structural shapes. To this must be added the tremendous amount of iron and steel entering into the construction of concrete plants all over the country and into their heavy machinery and equipment.

Exactly to what extent concrete has supplanted steel and to what extent it has indirectly created a demand for iron and steel can not, of couse, be determined. But the continued advance of the iron and steel business in connection with the giant strides in the building world offers ample evidence that the steelmaker has not suffered. Rather it is that as steel reinforcement has made concrete construction possible and practical the growing use of concrete has redounded to the advantage of steel in even greater degree.

DUTY ON STRUCTURAL IRON.

BEFORE the Tariff Commission in Ottawa last month a memorial signed by the Dominion Bridge Company, the Hamilton Bridge Company, the Canada Foundry Company and the Phoenix Iron Works, was presented, suggesting that the duty on structural metal work should be specific rather than ad valorem, and that in the revision of the tariff the duty on bridges and structural metal work be made $20 per ton, which would correspond to the present rate of 35 per cent. on material valued at $2.86 per hundred pounds. It was represented that the change asked for was necessary by reason of the United States competition, the manufacturers there selling in Canada below cost at every recurring period of depression. It was also asked that the duty on small structural parts, which at present is prohibitive, be fixed at 10 per cent. This will greatly increase the use of small parts, and consequently increase the demand for larger metal work, which these companies manufacture. The total capital invested is about five and a half millions of dollars.

Our Water Power

Works at Fort Frances.

ENORMOUS power development is being pushed to completion at Fort Frances, a view of which is given on this page. The big dam, in course of construction for some time, is progressing rapidly. It is expected that by Spring large coffer-dams will have been completed and work on the power house and pulp mill commenced. It has been stated by Mr. A. W. Backus, president of the company, that in addition to power house and pulp mill a large saw mill will be erected at Fort Frances.

Falls at Fort Frances, on Rainy River, New Ontario.

Already machinery has been installed for the cement works, which when completed will give employment to over 300 men. With water power assured, which is expected to be ready for delivery in August next, there is no doubt that a large number of industries will follow and place this town amongst the leading Canadian manufacturing centres.

Another Power Company.

The Niagara-Welland Power Co., whose object is to transmit power in Western Ontario and as far as Toronto, have taken active steps to prosecute their enterprise. The company propose to tap the Welland River at a point 4½ miles from the village of Chippewa, and to construct a canal six miles to a point under the Niagara escarpment near the township line between the townships of Stamford and Thorold in the county of Welland. The citizens of Toronto and other places will no doubt be glad to hear of competing lines supplying power to their respective cities. In developing this power more of the water at present flowing over Niagara will be utilized.

Preserving Niagara.

In the February Outlook Chas. M. Dow, president of the State Reservation at Niagara Falls, N.Y., published an article of interest to both Canada and the United States. He states the various conditions under which power is being at present developed, and the amount of same, by the different companies. He calculates that at present the authorized diversion of the waters of Niagara for power purposes totals 60,000 cubic feet per second, and makes an appeal to all lovers of Niagara to take an active interest in the direction of preventing any further utilization of the Niagara waters for power purposes.

Electrical Development Co. at Niagara.

During the visit to Niagara of the Canadian Society of Civil Engineers at the time of their annual convention slips were given out containing information relating to the hydraulic power plant of the Electrical Development Co. of Ontario. They showed that the area unwatered by the coffer-dam was 11 acres, length of coffer-dam 2,200 feet, length of overflow dam 736 feet, maximum width overflow dam 33 ft. 3 in.; calculated level of water in forebay, ele. 529.5; diameter of inlet pipes or penstocks, 10 ft. 6 in.; wheel pit, 416 feet long, 22 feet wide and ele. of bottom, 388.; effective head on wheels, 135 ft.; capacity of electric cranes, 25 and 80 tons respectively; diameter of draft tubes, 9 ft.; branch tail race tunnels, length, 1,040 feet; main tail race tunnel, from intersection of branch tunnels to outlet behind falls, 1,900 feet; main tail race tunnel is of Horseshoe section, 26½ feet high and 23 feet wide; main tail race tunnel, area of water way, 452 sq. ft.; main tail race tunnel, calculated velocity of water, 26 ft. per second; 11 turbines 12,500 h.-p. capacity double runners right and left inward and parallel flow, 250 rev. per minute; 11 generators, 8,000 k.w. generate at 12,000 volts stepped up to 60,000 volts for transmission to Toronto; line, 80 miles.

ABOUT CATALOGUES

By mentioning Canadian Machinery to show that you are in the trade, a copy of any of these catalogues will be sent by the firm whose address is given.

Rivets—The Parmenter & Bullock Co., Gananoque, Ont., standard lists show a wide range of these goods. 12 pages, 6 x 8 3-4.

Ratchet Drills. The Billings & Spencer Co., Hartford, Conn., are sending out a folding price list of their "Genuine Packer Ratchet Drills."

Making Projectiles. A pamphlet of the Gisholt Machine Co., Madison, Wis., describing the operations of a 24-inch Gisholt lathe in making steel projectiles. 7 1-2 x 9 1-2.

Canadian Westinghouse. Circulars No. 1127 and 1107 describe the Westinghouse automatic circuit breakers, and control apparatus and trolleys for single phase railway system.

Sawyer Man Lamps. A 28-page illustrated catalogue describing many lines of incandescent lamps manufactured by the Sawyer Man Electric Co., New York, and sold by the Westinghouse Electric Co.

Special Fans. A booklet issued by Sheldon & Sheldon, Galt, Ont., devoted to a condensed description of special asbestos fans, designed by this firm expressly for the asbestos mines of the Province of Quebec.

Hamilton Machine Tool Co. Catalogue No. 5 of the Hamilton Machine Tool Co. gives particulars about their planers and shapers. The catalogue contains 80 pages and is illustrated throughout with the finest half-tones. The corners of the pages are rounded, and the size is 9 inches by 6 inches.

Lamp Pointers. A paper by G. Brewer Griffin read before the Ohio Electric Light Association at their annual convention, issued by the Westinghouse Electric & Mfg. Co., Pittsburg. It takes up the different considerations to be gone into when purchasing series A. C. arc lamps. Twenty-six pages, 6 x 9.

Engines and Boilers. Forty-eight page catalogue, being the 15th annual issued by H. W. Petrie, Toronto, Ont., descriptive of the different classes of steam engines and boilers, handled by this firm. Each line is illustrated and described separately with full data of the dimensions and capacity thereof. Size 5 x 7.

Drills and Chucks. A neatly bound pamphlet with embossed cover, is the "bulletin" issued by the Geo. R. Rich Manufacturing Co., of Buchanan, Mich., to describe their drills and chucks. It is in the form of an essay on "Improved Machine Shop Tools and Appliances," which makes interesting reading.

Cement Bonding. The B. Greening Wire Co., Limited, have issued a catalogue descriptive of their new method of wire bonding associated with the use of concrete in building construction. This catalogue also contains information regarding wire lathing that is of interest to any in the building line. Twelve pages; size, 7 x 10.

E. W. Bliss Co. An 80-page catalogue of handy pocket size, has been issued by E. W. Bliss Co., of New York, dealing with their machinery for the manufacture of pieced tin, and black ironware. The whole is copiously illustrated, the cuts showing up finely on the coated paper which comprises the body of the book. It is full of interest for all those who are engaged in manufacturing the goods named.

Milling Machines. Catalogues of the Becker-Brainard Milling Machine Co., Hyde Park, Mass., include a catalogue of plain horizontal milling machines and universal milling machines, fully illustrated and well described. Size, 6 x 9. Another catalogue of 49 pages, describes very clearly the vertical milling machines made by this firm. In another catalogue of 98 pages is illustrated the different styles of milling cutters, besides sets of tables and complete data on car wheels, bevel gears, etc., besides weights, areas, standard sizes of high speed drills, and a wide range of other information. These may be had by application to the company mentioned. Size, 4 x 6 inches.

Beautiful Calendar. Allis-Chalmers-Bullock, Limited, Montreal, are sending out a beautifully lithographed monthly desk calendar. It is one of the best pieces of work of the year, being printed in nine colors. The great value of it, however, will be in the fact that each month the coat of arms of one of the provinces will be a feature of the card, and within the year recipient will have a complete and correct coat of arms of each province of Canada. The January card gives the coat of arms for Ontario. No doubt any reader may have a copy sent to him regularly—in fact they are well worth having—by dropping the company a postal card, stating that they are readers of Canadian Machinery.

BOOK REVIEWS.

Modern Engines and Power Generators, by Rankin Kennedy, C.E., in six volumes; $15.00 the set. Toronto: Morang & Co., publishers.

This series of volumes constitutes a practical work on prime movers and the transmission of power by steam, electricity, water and hot air. The author is already well known as the writer of several standard technical books, so that in looking forward to this work, a high standard is expected and the reader is not disappointed. The collecting of all the data, information and illustrations published in these volumes by one man was a stupendous task, but the effort has been well directed, as shown in the output. The object of the work is to explain in a most thorough manner the design and construction of modern prime movers, and to explain in detail the peculiarities of each. Besides this, it aims to go into particulars to the extent of enabling any practical engineer to understand and construct the engine, boiler, etc., from the description given, as well as to enable him to estimate in each case the costs of producing power under the different systems and circumstances. As well as the prime movers, the different methods of transmitting the power from the prime mover to the work to be done are discussed.

One of the pleasing features in connection with this book, inasmuch as it is designed to be practical, is its simplicity that enables one to read it without a particular knowledge of mathematical mechanics or thermodynamics. Besides taking up the construction, the author explains thoroughly the working of the different engines. The part relating to gas generators and gas plants is particularly valuable. To go into a review of these six volumes would be impossible, but it might be mentioned that for anyone in the engineering profession or in the mechanical trade, who would become more intimate with the different prime movers in which he comes in contact, these volumes should prove a veritable encyclopedia.

At the Noon Hour

He Was Fired.

A builder in Pennsylvania, having heard that the men did not start work at the proper time, thought he would drop down about 6.30 one morning and see. Going up to the yard he caught sight of a joiner standing smoking, with

If you are grouchy, here is what you are coming to. This man grumbled about poor tools, his meals, the weather. This became chronic until he is a misfit in the universe.

his kit not even opened. Simply asking his name, which he found to be Jake Robertson, he called him into the office, and handing him four days' pay told him to leave at once.

After having seen the man clear of the yard, he went up to the foreman and told him he had made an example of Jake Robertson by paying him off for not starting to work at the proper hour.

"Jumping Jupiter," ejaculated the foreman, "that chap was only looking for a job."—N. Y. World.

Reason of Boycott.

Of an Irishman on the sidewalk stating to passersby that the corner grocery was boycotted by the union, one of them asked the reason of the boycott. "Well," said the Irishman, scratching his head, "I don't know exactly how it is, but it is about like this : Hogan—Hogan keeps the grocery—Hogan had a partition built in his store and he got a carpenter to build it that bought a new saw from that old white-haired duffer that rides around in the carriage, and the old white-haired duffer's coachman that rides around with him in the carriage had took his collars to a laundry that hired a non-union painter to put in new glass where the window had been broken. So they boycotted Hogan's grocery."—Fuel.

His Not to Reason Why.

The inefficiency of Mexican labor was under discussion by a group of mining promoters.

"On my last trip to Mexico," said one, "while our train halted at Jimulco, a dinner station on the Mexican Central, I alighted and watched the mechanic who went from car to car sounding the wheels with a hammer, presumably to test their condition. He was a fair type of a native 'skilled workman.' Just to draw him out a little, I inquired—

" 'Why do you rap the wheels ?'

"Setting down his torch, he stared at me in amazement. 'Because the master mechanic tells me to,' he replied.

" 'But, why ?' I persisted. 'What good does it do ?'

" 'I do not know, senor,' said he. 'The master mechanic tells me to strike each wheel, and I do so. That is enough for me.'

" 'How long have you been working at this job ?' I asked.

" 'Two years,' he replied. For two years he had been going through the form of sounding the car wheels, without the slightest knowledge of the object of the test or the slightest curiosity concerning it !"—Philadelphia Record.

At Home.

The Latest Shade—When on earth I was an automobilist.

His Satanic Majesty—Ah ! Then please be kind enough to crawl under that furnace and see what's the matter with the grate ; it seems to be klinked up.—Ex.

Honesty's Vacation.

Diogenes was reflecting. His quest for an honest man had failed. Suddenly his face brightened.

"Well, that's one on me," he said. "I might have known that between the investigations of insurance and of oil they'd all be driven out of town."

"'Tis easy enough to be pleasant
When life rolls on like a song ;
But the man worth while is the man who can smile
When everything goes dead wrong."

Putting a fresh candle in his lantern he started for the tall timber.—News.

Tricks of the Trade.

Everybody is invited to contribute to this page. Send in your ideas, odd jobs you are doing, and anything of interest to fellow-workmen. Remuneration will be made for such contributions. [Ed.]

Novel Gear Cutting.

HAVING occasion to cut an irregular box cam without being particularly prepared for such a job, a novel means was adopted for effecting this, with the aid of an air drill, as will be seen from the illustration. The cam itself, it may be noticed, is so fashioned

The Finished Cam.

that at one point the groove is located very close to the centre of the gear, while it runs close to the rim at another point, hence it could not be cut with a single tool, it being absolutely necessary that the groove of the cam be parallel.

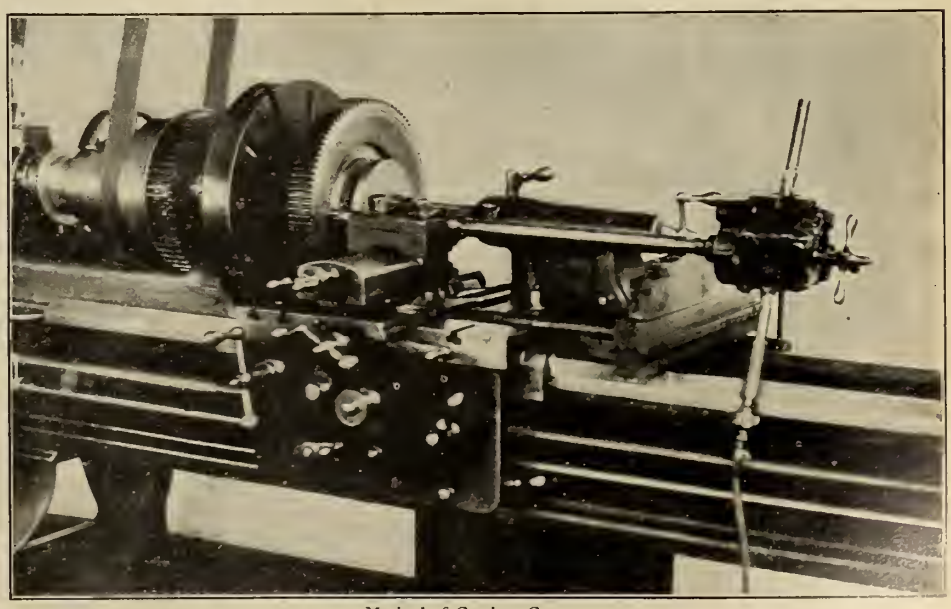
The method devised, in lieu of the particular apparatus necessary, and which turned out particularly successful in this emergency, consisted of a block mounted on the slide of engine lathe in which a milling cutter was free to revolve. A master cam was attached to mandrel with gear in proper relation to it ; as the lathe revolved slowly (the slide rest having previously been disconnected from the cross feed screw) the milling cutter was kept in contact with the master cam by means of a weight fastened to the end of cross feed slide. The cutter arbor in contact with the master cam was the same diameter as the milling cutter used ; this insured an absolutely parallel slot. A pneumatic drill was used for driving the cutter. This arrangement proved to be a satisfactory one in every respect, as the speed could be controlled to a nicety. It made the fixture at minimum cost, no cumbersome belts or other complicated mechanism being necessary and the set up required no more time than an ordinary chucking job.—Henry J. Kimman, superintendent of the Cleveland plant, Chicago Pneumatic Tool Co.

Something to Invent.

It is not an uncommon occurrence to hear a mechanic remark that "if he could only think of something to invent he would soon jump his overalls and leave that class of work for some one else to do."

It appears to me that such a person is trying to jump from the bottom to the top of the ladder without climbing its intermediate steps or trying to grasp from futurity something that is not meant for this stage of the world's history. There is an old saying, ;'Necessity is the mother of invention." It seems to me absurd for a person to invent some new contrivance and then have to look for something to apply it to.

There are any number of places where he could begin, the most of which are so common and simple that for that very reason they are usually overlooked. Take for instance the efficiency of our common steam engines, ranging from 60 to 80 per cent. Does it ever cross his mind that there is room for improvement there ? He may say that it has got to have bearings large enough to withstand the greatest strain or that it has to have a piston with stroke and area enough to do the work. These facts are quite true, but are there no ways of improving the condition and thus raise the efficiency of the engine ? — no more effective method of lubricating those bearings and cylinder or no better



Method of Cutting Cam.

contrivance than the present form of piston with its stiff rings pressing hard against the walls of the cylinder ? He may say, "That is so. I never thought of that." I therefore think it would be a good idea to urge the readers of Canadian Machinery to follow more in detail the steady progress that is being made in improving what we have already got and to expend their time and brains on a class of work that lies within the range of their ability.—G. P. Johnston, Hamilton.

To Clean a File.

Those who have had to file any of the softer alloys of aluminum know what a clinging and leady substance it is under the file. In the opinion of many it is the worst stock to file, without exception, of commercial metals, and files clogged with aluminum are difficult to clean with the scratch brush. The writer has found that an ordinary file stuck up with aluminum can be readily cleaned with the brush by first dipping the file for a few minutes in a rather strong solution of caustic potash or soda lye, or failing this a smear of soft soap, which usually contains an excess of potash. It may be explained that the caustic alkalies have a strong affinity for metallic aluminum, evolving hydrogen and forming aluminates, allied to clay.

In France they have on the market a special file with a tooth expressly designed for soft alloys and gun metal, which partakes somewhat of the same clogging nature, and the tendency to roll up "pin heads." It is said these special cut files save much time and do better work in factories especially devoted to working such metals, but in ordinary jobbing practice a knowledge of this weak spot of aluminum serves as well, and should be added to the list of "shop kinks" that fill up the trade of every tried and capable machinist. — C. J. Stuart, Montreal.

Power and Transmission

Steam Gas Electricity Compressed Air Water

IMPROVEMENTS IN THE ROBB-ARMSTRONG ENGINE.

IN order to keep abreast with the improvements in machine building that have been developed in recent years, the Robb Engineering Co., Limited, of Amherst, Nova Scotia, is constantly bettering the design of its product, retaining the good features of the older engines and adding numerous improvements suggested by accumulated experience in the work. The accompanying illustration shows the general design and construction of a medium speed Corliss type of engine, which is a single cylinder, Corliss, of the heavy duty type, with outboard bearing on an independent pedestal. The frame has great strength and rigidity, and this is obtained by a careful disposition of the metal and by the use of liberal thickness where weight is of benefit. It is averred that under the heaviest load, there is no evidence of strain.

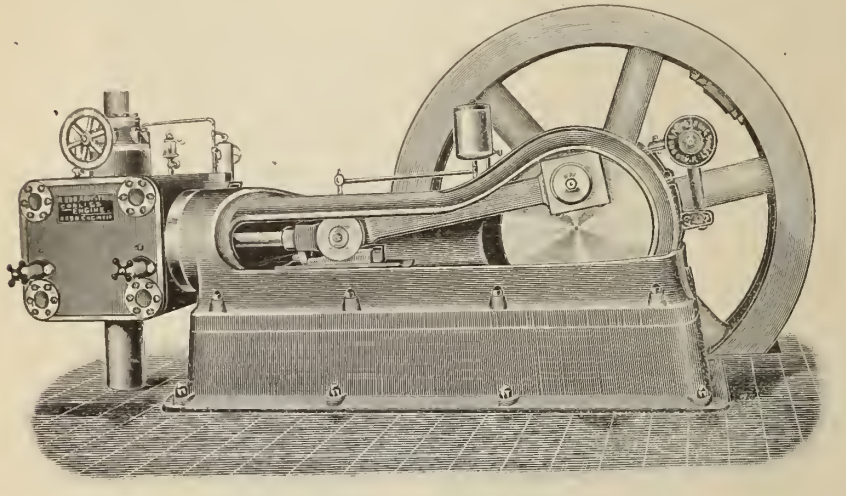


Fig. 1 Medium Speed Heavy Duty Robb-Armstrong Engine

These Corliss engines are built in two types, known as the medium speed, heavy duty type, and the slow speed, known as type F. The latter engine embodies all the features of the former, but is of longer stroke and designed for slower speed.

The special features of the Robb-Armstrong engines are the Armstrong Corliss valve gear, which is more simple in construction than the ordinary releasing gear, and will operate successfully for any speed up to 200 revolutions per minute. By the introduction of two small links between the wrist plate and bell cranks, the steam valves are caused to open and close quickly and remain stationary during the remainder of the stroke, the action of the valves and steam distribution being almost precisely the same as the releasing gear invented by Mr. George H. Corliss, the advantage being that as the Armstrong gear is positively driven, and does not depend on springs or dash pots used in the ordinary Corliss valve gear, it may be operated at much higher speed than the releasing gear, and as there are only about half as many pieces and wearing surfaces, and no latches or detachable parts, and as all the parts, with the exception of the bell cranks, are encased in oil, the gear runs very smoothly without noise, friction or wear. The valves are of the usual Corliss rotative type, but of the latest design, partially balanced and triple ported, giving very short travel and quick opening. The exhaust valves are driven from a wrist plate in the usual way.

The governor, Fig. 2, is the Robb-Armstrong-Sweet design, the centrifugal weight being carried directly by a spring, so that the heavy strain due to centrifugal force is not brought on the suspension pin, which merely carries the ec-

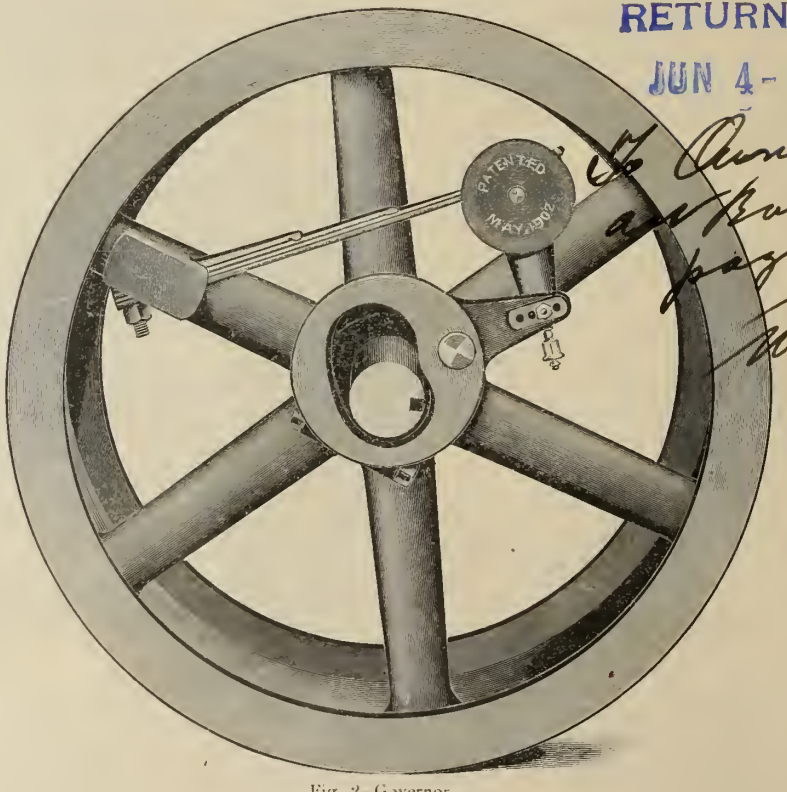

Fig. 2 Governor.

RETURNED
JUN 4 - 1906

eentric, and is not subject to any strain or friction except that due to driving the valve gear. The governor system is in gravity balance in all positions, be-

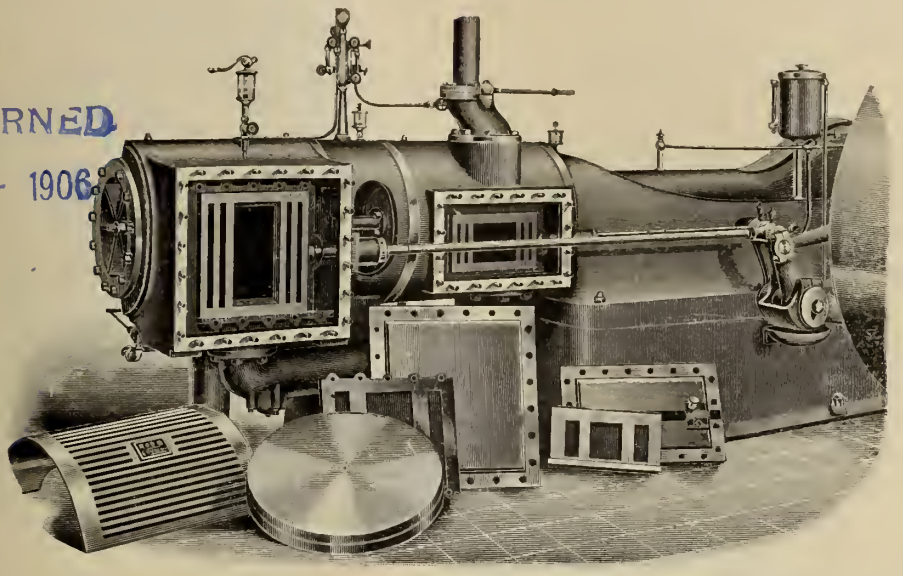

Fig. 3—Robb-Armstrong Engine, showing valve seat.

cause the eccentrie is made to balance the centrifugal weight, this principle being the same as that used by Professor John E. Sweet in the governor of his straight line engines. The speed is raised or lowered by ehanging the tension of the spring, and the sensitiveness is controlled by moving the liuk which eonnects the weight and the eccentric in or out, along the row of holes provided for that purpose. This governor can be made to regulate so accurately through a large range and with so little friction, that it is especially recommended for engines driving alternating current generators in parallel. All the working bearings are oiled by a forced-feed system. This system consists of a pump which is attached to the eccentric, driven from the crank pin. The pump is located in the crank pit, which is made deep and used as an oil reservoir, the oil returning to the crank pit from a filter, whence it is pumped back to the bearings, thus supplying a continuous circulation of oil.

The pump is simplicity itself, as there are no valves, stuffing boxes or other objectionable features which are liable to get out of order and clog. It consists merely of a steel plunger, which fits into a brass sleeve and oscillates. In the larger engines, the pump is made of sufficient size to keep a constant pressure of from 12 to 15 pounds on the bearings. A small pressure gauge is provided. This system has the advantage over the gravity system, and also the splash system, that it keeps a continuous, positive, forced feed eirculation of oil in all the bearings. Experienee with high speed engines of British manufacture demonstrated that with this system, of forced lubrication, an engine will run continuously with practically no wear and absolutely noiseless.

The parts covered by the foregoing description are practically alike for all sizes of engines, with the exception of the high speed and smaller engines, in which the Sweet balanced valve is used. The valve seat in the cylinders, Fig. 3, the pressure plate, and the distance strip are accurately finished. In this valve, practically the only wear is downward. These engines, both of the single valve and four valve types are built either vertical or horizontal, simple or compound. Figs. 4 and 5 are recent installations of Robb-Armstrong engines in Canadian power houses.

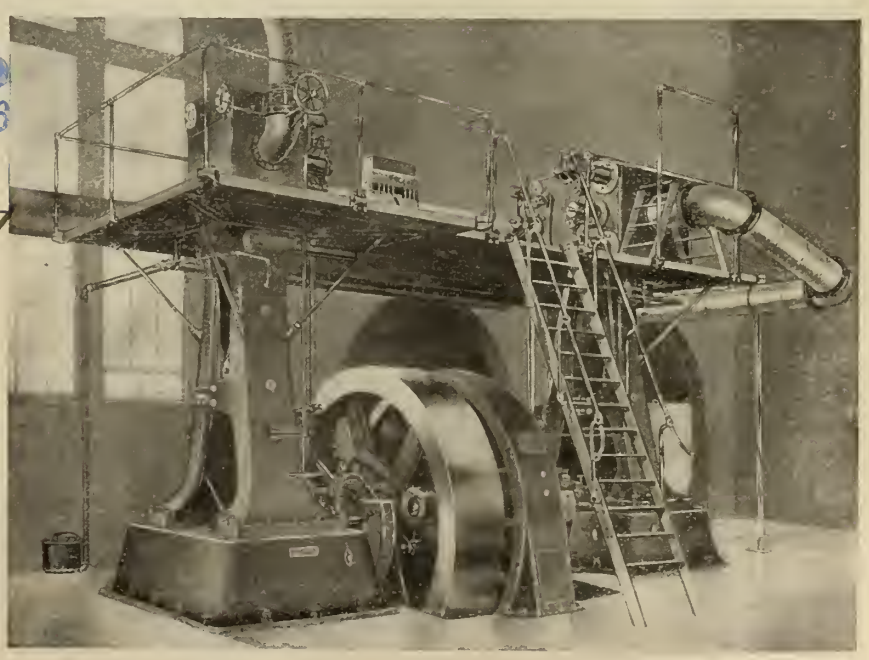

Fig. 4.

A LARGE STEAM TURBINE GENERATOR.

ACCORDING to B. A. Behrend, chief electrical engineer of the Allis-Chalmers Co., a generator of 5,500 k.w., direct connected to a steam turbine, was recently tested at the Bullock works, at Cincinnati, of the Allis-Chalmers Co. This machine and its performanee are interesting on account of numerous novel features, as well as on account of the high efficiency, perfect regulation, and low temperature, which have been brought out by tests. Although the normal rated eapaeity of this generator is 5,500 k.w., at either 6,600 or 11,000 volts, the generator must be capable of standing 6,880 k.w. continuously without rising more than 45 degrees C., and 8,250 k.w. for three hours without rising more than 55 degrees C. On the overload this generator, therefore, will require a prime mover developing 11,500 h.p.

The current developed by this machine has 25 periods, is three-phase, and is generated by a 4-pole magnetie field turning at 750 revolutions per minute. Fig. 1 shows the stationary eore or armature, and Fig. 2 the rotating element. Fig. 1 gives a good view of the thorough lamination and division of the stator core for the purpose of ventila-

tion and cooling, while Fig. 2 shows the most interesting part of the machine, namely, the rotating field. When we stop to consider that the peripheral speed of the surface of this rotating field is almost 15,000 feet per minute, we realize that we have before us a problem taxing the designing ability of the engineer to the utmost. If we could proceed, either on railroads or on the ocean, at such speeds as this, we should travel from New York to London in approximately 17 hours. Under such conditions of speed the centrifugal force assumes tremendous magnitude; and the careful distribution and calculation of the stresses and strains in the different members of the rotating magnetic field become a matter of the utmost importance and seriousness. The bursting of a mass of steel, of 75,000 pounds, rotating at the rate of 3 miles per minute, would produce very disastrous effects, and the responsibility of the designer and builder of such machines is, therefore, a very grave matter.

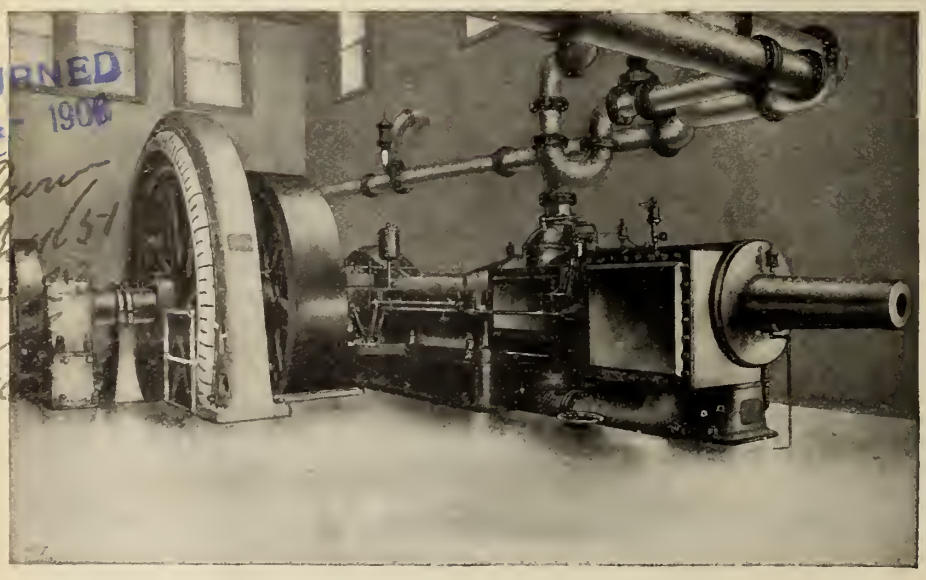

Fig. 5.

A careful investigation in regard to the stresses and strains produced in rotating discs under the influence of centrifugal force was carried out by the writer several years ago, theoretically as well as experimentally, and it brought forth the interesting result that, in a plain rotating disc, the stresses are a maximum on the inside boundary of the disc, and a minimum on the outside boundary. These results, obtained by mathematical analysis, were borne out by experiments on lead discs, the distortion of which was carefully studied by measuring the discs before the speed tests and after, and the distortion corroborated the correctness of the theoretical conclusions. Rotating discs, therefore, really do "burst" when they go to pieces, that is, they explode in such a manner that they are rent to pieces by forces which tear the fibre of the material, first on the inside, the rents rapidly being transmitted to the outside. This investigation is of considerable interest with regard to the bursting of emery wheels and grindstones, and it throws much light upon the proper and economical design of wheels of any kind, rotating at high speeds. With the aid of the data obtained through these theoretical and experimental investigations, the foundation of design of the rotating elements of these large machines has become well secured, and the determination of the maximum internal stresses in the nickel-steel plates composing the rotating field, illustrated in Fig. 2, can be made with considerable confidence. The structure of the rotating field consists of ten nickel-steel forgings pressed on a nickel-steel shaft. In order to obtain both high magnetic permeability and good mechanical strength, nickel-steel, containing approximately from 3 to 5 per cent. nickel, has been used whose lowest elastic limit is 50,000 pounds per square inch, and whose lowest ultimate strength is 80,000 pounds per square inch. The highest stress existing in any one part of the rotating element does not exceed 15,000 pounds per square inch. At normal speed, therefore, the lowest safety factor is almost 5½, showing that these rotating fields might be run at twice their normal speed without flying asunder.

A problem of extreme difficulty confronts the designer in placing and securely fastening the field windings to these large steel blocks in such a manner that neither the copper conductors nor the insulation between them and the magnetic field can be injured by the centrifugal force to which they are exposed. To this end flat copper strips have been wound on specially designed formers, which are made in such a manner as to give an ever-increasing opening to each successive turn, and they are lodged in radial slots, milled into the nickel-steel discs, and held in place by retaining wedges made from Parsons manganese bronze. The construction is so solid that it might well be said that a cannon could not be made stronger and more reliable. The end connections of the field coils rest against nickel-steel end rings, which also are shown in Fig. 2.

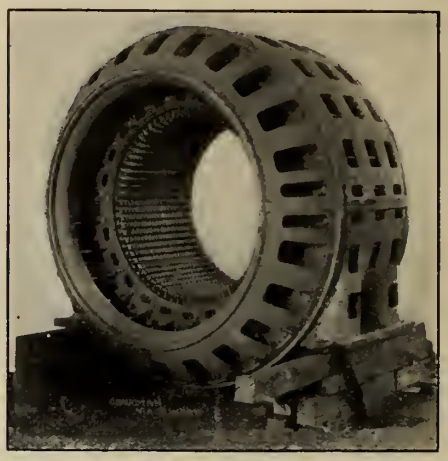

Fig. 1—Stationary Core or Armature.

The electrical efficiency of this generator, as actually obtained from tests, is 94.4 per cent. at ¼ load; 97 per cent. at ½ load; 97.9 per cent. at ¾ load; 98.3 per cent. at full load; 98.5 per cent. at 1¼ load, and 98.6 per cent. at 1½ load. The regulation of the generator at full load at 100 per cent. power factor is 7½ per cent., and yet the generator has enough margin to give its full rated output on any power factor, however low.

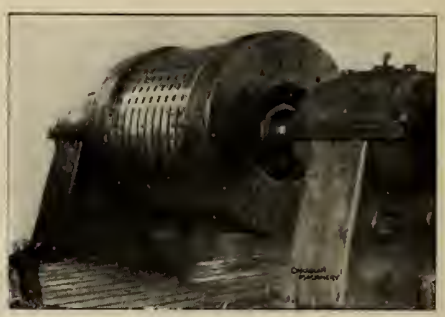

Fig. 2—The Rotating Element.

'TWAS A SHELDON SYSTEM.

In the write-up of the Davidson & Thackray plant in last issue it was mentioned that the dry kiln was operated by the Sturtevant fan system. This was published in good faith as the in-

formation was secured first-hand at the works being described. However, it should have read Sheldon & Sheldon, as this firm designed the entire drying systems for the kilns, which are the largest of their kind in Canada.

Plan of Green Air Heater and Economizer Installation.

THE GREEN AIR HEATER.

AN air heater has recently been developed by the Green Fuel Economizer Co. similar in many respects to the economizer and installed after the same manner. Air is drawn in at the top by means of a fan and forced first down through one set of tubes, up through another set, then down, and so on until it leaves the heater to be distributed by pipes to drying chambers, and other places in which the heated air is used.

The tubes are of cast iron and are nine feet long between the headers and have an internal diameter of 3⅞ inches. They are hydraulically pressed into top and bottom boxes which are of sloping design, in order to insure uniform velocity and distribution of the air in passing from one set of tubes to the next. The air moves through the tubes at a high rate of speed, and by the frequent redistribution to the tubes all possibility of short-circuiting or eddying is eliminated. This results in a high efficiency of the heating surface. Separate top and bottom boxes are provided for each row of tubes, so that any number of rows may be set up together for any capacity of plant or any gases pass into the chimney, while the heated air is taken out at the end nearest the boiler, where the flue gases are at their highest temperature. This causes a uniform difference of temperature to be maintained between the flue gases and the air in the tubes. The air heater may be combined with the economizer and a test made on a plant of this kind, which contained 144 economizer tubes and 72 heater tubes, gave the following results :

Temperature of gases entering economizer, 460 deg. F.

Temperature of gases entering air heater, 301 deg. F.

Temperature of gases leaving air heater, 257 deg. F.

Temperature of water entering economizer, 112 deg. F.

Temperature of water leaving economizer, 248 deg. F.

Temperature of air entering air heater, 70 deg. F.

Temperature of air leaving air heater, 152 deg. F.

It will be noted that the air left the heater at the temperature of 152 degrees F. Air at this temperature will take up nearly 0.01 pound of water per cubic foot, making it very effective for drying purposes.

This heater will replace steam heater coils for drying, thereby saving as much steam as will be required for drying and the corresponding amount of fuel, also relieving the boiler plant of this demand for steam. It thereby increases, by this amount, the capacity of the plant.

USEFULNESS OF GRAPHITE.

GRAPHITE is one of the purest forms in which carbon occurs in nature. It is bright in lustre, soft and smooth. It is not affected by heat or cold, and is not acted upon by acids or alkalies.

It occurs naturally in two forms, the flake (or foliated) and amorphous. Comparing the one with the other there is a vast difference in nature, texture, action and effect. In the first place "flake" graphite is not adhesive, and adhesiveness is absolutely essential as an efficient lubricant.

The ideal lubricant should get at the cause of friction. Friction is due to the roughness and unevenness of the surfaces in contact. And this friction, of course, means wasted energy that, instead of being utilized as power, is absorbed as heat. No matter how smooth the surface may appear to the naked eye, it will always prove to be rough and full of inequalities when examined under the microscope. To effectively overcome this friction, to permanently fill up all the minute roughness of the metal surfaces, and utilize the wasted

RETURNED

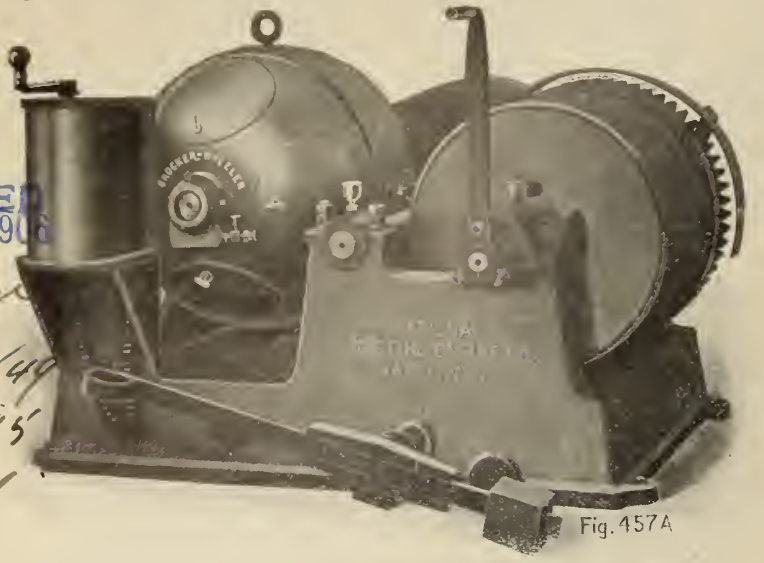
Installation Comprising Green Air Heater and Green Fuel Economizer.

power, a substantial lubricant is required.

Canada's new lubricating graphite is an impalpable, "air-floated" powder—atoms rather than flakes—with its natural affinity to fluids, readily mixes with oil, and remains in almost perfect suspension, resulting in the increased efficiency and life of the oil. A thinner and cheaper oil may be used, and the consumption reduced at least one-fourth, and in many cases one-third, thus making a great saving in cost of lubricating materials, at the same time securing absolute freedom from hot bearings. It is manufactured by the Economical Supply Co., 173 Queen street east, Toronto.



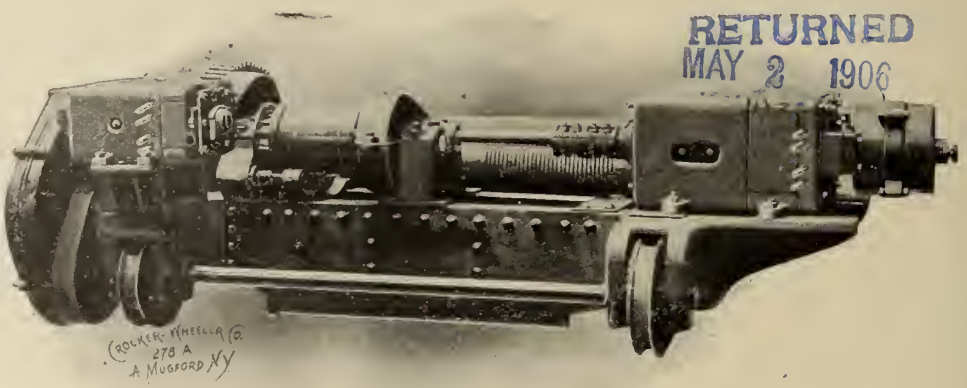
rocker-Wheeler Standard Electric Hoist.

ELECTRIC HOISTING MACHINERY.

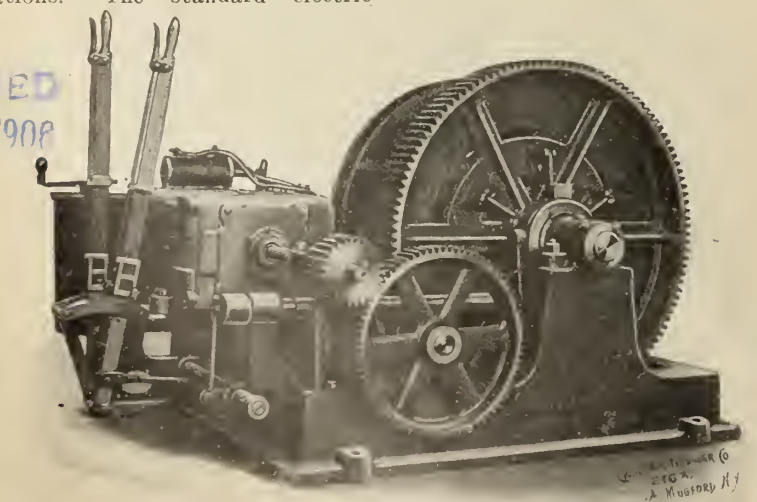
SOME of the adaptations of the Crocker-Wheeler motors to hoisting machinery are shown in three illustrations. The standard electric hoist is provided with a winding drum driven by the motor through a double run of spur gearing. This drum is free to revolve on the shaft, but is thrown into engagement with the gearing by means of a friction clutch operated by a hand lever. When the drum is disengaged from the clutch, its motion may be regulated or stopped by means of a band brake operated by a foot lever.

The motor is operated by a reversible drum controller, providing twelve or more speeds in either direction, and the location of the controller handle, foot lever and friction lever, is such as to place them all within convenient reach of the operator. The motor is of the fully enclosed I type, having a compound winding especially suited to this class of work.

In operation, the motor may be run continuously and the motion of the drum controlled by means of the friction clutch and band brake, or when the class of service demands, the friction clutch may be engaged and the motion of the drum regulated by the controller.



Crocker-Wheeler Motors Operating Traveling Crane.



Motor Operating Prospecting Hoist.

MECHANICAL DRAFT.

THE advantages of mechanical draft are thus presented in the new work on "Smoke Abatement," by Wm. Nicholson :

"1. If the boilers are well constructed and are provided with ample room to insure circulation, their steaming power may, without injury, be increased to 30 per cent. over that obtained by the natural draft for continuous working. 2. Such augmentation is accompanied in normal cases by an increased consumption per indicated horse power. 3. It enables an inferior fuel to be used. 4. Under certain conditions of weather it would be difficult to maintain steam with natural draft, but with forced draft the power is insured. 5. Much thicker fires can be worked than with natural draft, causing the air to travel through incandescent fuel, with more time to give up its oxygen, while the intensity of the draft through the incandescent fuel causes a more intimate mixing of the air with it than is possible with ordinary chimney draft."

ENGINEERING NEWS

AND SOCIETY NOTES

SOCIETY OFFICERS.

Canadian Mining Institute.

President, George R. Smith, Thetford Mines, Quebec; secretary, H. Mortimer Lamb, Victoria, B.C.; treasurer, J. Stevenson Brown, Montreal.

Toronto Branch A. I. E. E.

Chairman, H. A. Moore; vice-chairman, R. G. Black; secretary, R. T. McKeen.

Marine Engineers.

Grand president, E. J. Henning, Toronto; grand secretary, Neil J. Morrison, St. John, N.B.

Engineers' Society, Faculty Applied Science, Toronto University.

President, T. R. Loudon; recording secretary, F. A. McGivern; treasurer, B. W. Marrs; corresponding secretary, C. S. Shirriss.

Canadian Electrical Association.

President, A. A. Wright, M.P., Renfrew, Ont; vice-presidents, R. G. Black, Toronto, John Murphy, Ottawa; secretary-treasurer, C. H. Mortimer, Confederation Life Building, Toronto.

Canadian Association of Stationary Engineers.

President, Wm A. Sweet, Hamilton; vice-president, Jos. Ironsides; secretary, Wm. Outhwaite, Toronto, conductor, Ed. Grandbois, Chatham; doorkeeper, Chas. Kelly, Chatham.

Ontario Association of Stationary Engineers.

President, Geo. Fowler, Toronto; vice-president, W. F. Chapman, Brockville; treasurer, Charles Moseley, Toronto; registrar, W. G. Blackgrove, Toronto.

CIVIL ENGINEERS' ANNUAL CONVENTION.

FOR the first time in its history the Canadian Society of Civil Engineers held its annual convention outside of Montreal, where the headquarters of the society are situated, the occasion being the twentieth annual gathering which was held at the King Edward Hotel, Toronto. A Toronto branch of the Canadian society has been proposed, and some strong sentiment in the direction of such a proposal expressed.

Canadian Society of Civil Engineers' Twentieth Annual Convention at Niagara Falls, Wednesday, Jan. 31st, 1906

The convention lasted four days, from January 30 to February 2 inclusive.

The ballot resulted in the following officers being elected: President, H. D. Lumsden, Ottawa; vice-presidents, M. J. Butler, of Ottawa, C. B. Smith, of Toronto, and W. M. Walbank, of Montreal; councillors, W. F. Tye, of Montreal; John Galbraith, of Toronto; Duncan Macpherson, of Ottawa; Phelps Johnson, of Montreal; W. H. MacLeod, of Winnipeg; G. H. Webster, of Manitoba; R. McColl, of Halifax; H. Holgate, of Montreal; John Kennedy, of Montreal; C. Fergie, of Sydney, C.B.; E. A. Hoare, of Quebec; J. S. Dennis, of Calgary; E. Mohun, of Vancouver; R. A. Ross, of Montreal; L. A. Herdt, of Montreal; R. J. Durley, J. E. Hardman, J. B. Porter, and J. G. G. Kerry, of Montreal.

A strong plea was made to the Dominion Government for more effective survey work being carried on in the different departments of the Government. Among the papers read at the different meetings were: "Diamond Mining at Kimberley, South Africa," by Prof. J. B. Porter, of Montreal; "Hydraulic Locks on the Trent Canal," by W. J. Francis, of Peterboro; "Experience with Conduits in Toronto, with Notes on the Laying of a 6-foot Steel Pipe," by C. L. Fellowes of Toronto. A paper, "Tide Levels and Datum Planes on the Pacific Coast of Canada," by Dr. Dawson, of Ottawa, was presented but time did not permit of its reading. The presidential address by E. Marceau, of Montreal, was on the subject of "The Origin of Our Canal System," being an interesting account of the different canals in Canada. One of the most pleasant features of the convention was a visit to Niagara Falls on a special train provided by the Grand Trunk Railway, where the society were the guests of the Ontario Niagara Power Co. The latter entertained the members to an elaborate banquet in their transformer station, which was beautifully decorated, the entire menu course having been cooked by electricity. During the day visits were made to the different power stations and the various developments inspected. On the last day of the convention the members visited in groups the transformer station of the Toronto & Niagara Power Co., Polson Iron Works, Canadian Shipbuilding Co., Toronto city pumping station, street railway power house, Electric Light Co., Consumers' Gas Co. and the Canada Foundry Co. At the latter place the members were banqueted by the officials of the company.

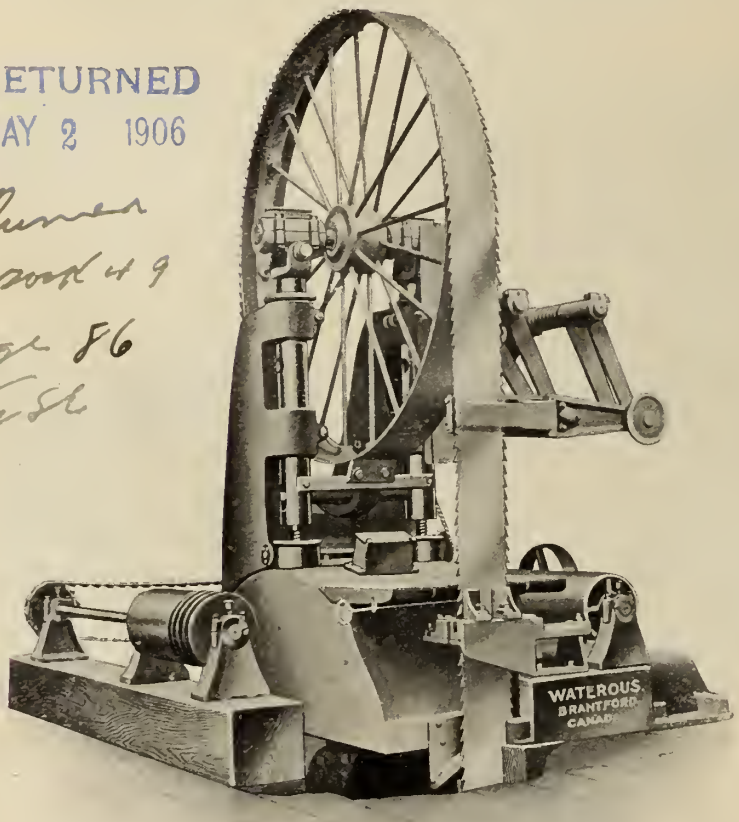
Machinery Development

Metal Working **Special Apparatus** **Wood Working**

PONY BAND SAW.

SINCE placing their first band saw on the market the Waterous Engine Works Co., of Brantford, have made important improvements and such additions as were found would make it not only a first-class band mill but would give it qualities as to actually render it capable of cutting as much or more than the large eight-foot band mill on small logs.

RETURNED
MAY 2 1906



Waterous Pony Band Saw.

The mill is being used for cutting pine, basswood, cottonwood and all classes of hard wood, both here and abroad. It is built and designed to occupy the place of the smaller circular saw mill. The mill is so constructed and arranged that it can be removed from place to place without incurring a very heavy expense. The lower frame is a strong arch casting 7 feet wide by 5 feet long. The lower wheel has full web, is turned all over to secure perfect balance, is bolted to a large flange on the mandrel—no keys to throw the face of wheel out of true with shaft axis. The boxes are ball and socket construction with liberal surfaces, and provided with large oil pots. The column carrying the upper wheel frame is box-shaped. The mandrel for upper wheel runs in two self-oiling boxes, one of which can be raised or lowered for tilting, and moved in or out of line for cross lining. The upper wheel has cast iron hub and rim connected by 22 steel spokes, staggered in both wheel and rim, is held on the heavy arbor with feather key and collars. The face of wheel is ground, on its own arbor, to the exact diameter in a special machine. The upper saw guide is of the safety pattern, it raises clear when struck by the log or knee, and is balanced. The tension or straining device is perfect and acts quickly, taking care of the saw blade (which is only 34 feet 6 inches long) under all conditions, thus enabling the use of thinner blades than in the ordinary band mill. The distance between upper and lower saw guides is 36 inches, falling down space 30 inches, so that even large sized logs can be worked up on this mill without difficulty. The single cutting mill has a live roll in the bed, driven from the lower mandrel. The driving pulley on mandrel is 32-inch diameter by 12-inch face, turning 450 to 500 revolutions; speed of saw depends on kind of lumber to be cut.

BACK GEARED CRANK SHAPER.

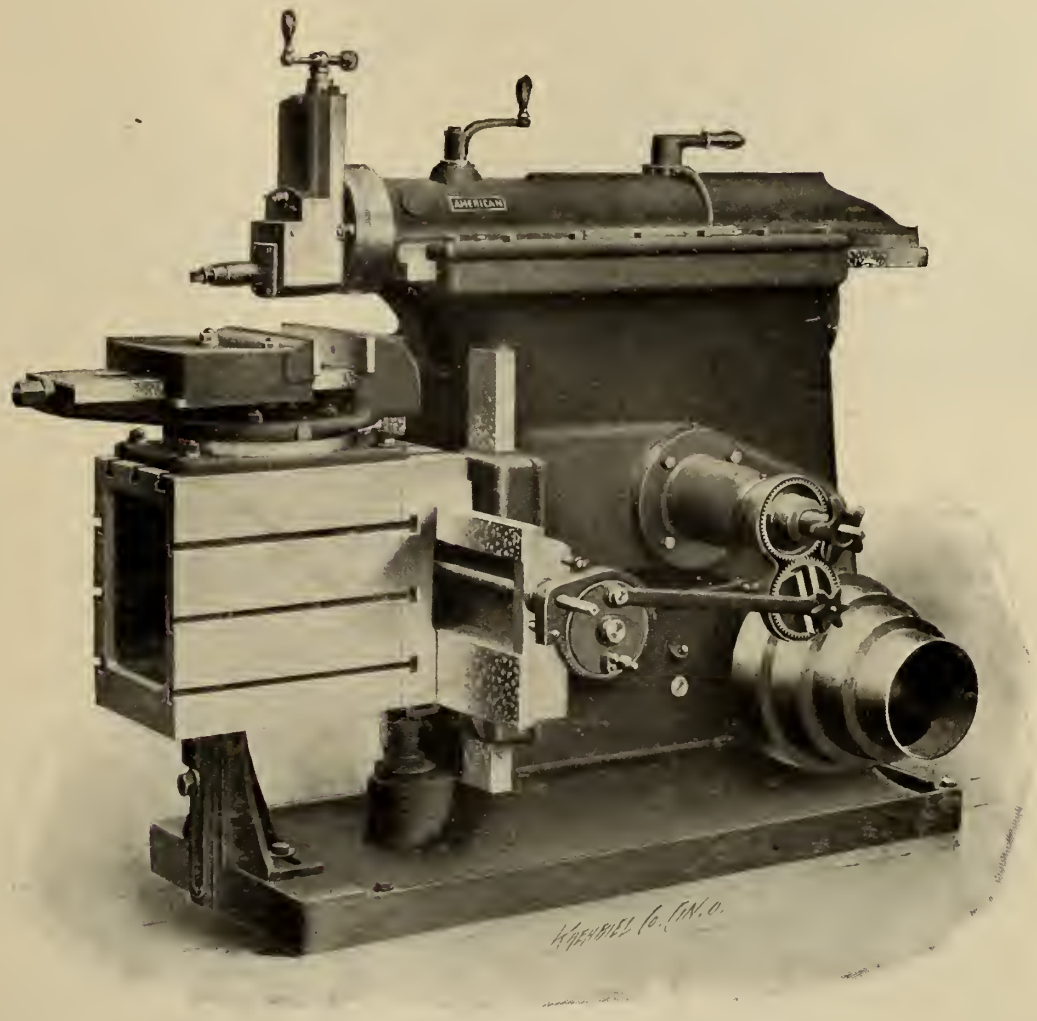
MODERN methods in shop practice and the extensive use of the new high speed tool steels have greatly increased the demands and duties now imposed upon shapers. The shaper, heretofore regarded as essentially a tool-room machine, has been made a manufacturing machine. To meet these changed conditions and new demands the American Tool Works have developed and built an entirely new line of extra heavy and powerful shapers.

The column is unusually deep and wide, tapering slightly towards the top, giving the machine a neat, graceful and substantial appearance. It is strongly braced internally, braces being so disposed as to meet the heaviest strain. The column is further reinforced outside on the line of strain by a wide, deep rib cast integral with the wall, projects both front and rear at the top providing an exceptionally long bearing for the ram. Base is of large proportions, strongly ribbed, of extension type with pad at end to receive table support, when same is furnished. Is of pan construction to hold oil drippings, thus protecting the floor. Stroke of ram is positive and has eight rates of speed ranging from 15 feet to 181½ feet. The length of stroke may be changed at will without stopping the machine. The device for positioning the stroke is located near the head and may be operated while the machine is running. A pointer on the ram traveling along an index shows the length of stroke as set. Rocker arm is extra heavy, thoroughly braced and pivoted near the base line, giving the ram an almost uniform rate of speed its entire stroke and providing an exceedingly quick return. The machine is readily changed from single to back

geared through a convenient lever and has the remarkable back gear ratio of 1 to 29.4, giving it extraordinary power for taking heavy cuts. Head swivels to 50 degrees and has improved locking device. Slide is fitted with taper gib for taking up the wear. Has down feed of unusual length, feed screw having an adjustable graduated collar reading to .001 in. Has large tool post for using holders with inserted cutters and has tool steel tool post screw and steel serrated back plate. Table is of box form with T-slots on the top and sides, cut from the solid with ample allowance of metal around them. Is thoroughly braced internally, insuring great rigidity. Is fitted to apron by an improved method insuring accuracy and great stiffness, and is readily detachable. Apron is accurately fitted to cross rail and is provided with taper gib for taking up the wear. Has three T-slots on face for clamping work when table is removed. Crossrail is a box form very heavy and strongly ribbed. Is of exceptional length, giving the table a long horizontal range of travel. Has extra wide bearings for apron scraped to surface plate. Is secured to column ways by clamps and bolts of improved design which prevent crossrail from dropping away when the binder bolts are loosed. A telescopic elevating screw of large diameter is provided with ball bearings for making easy the elevation of rail. This enables the machine to be set on a concrete or other floor without requiring a hole through same to accommodate the travel of the screw. Elevating gears are of steel planed from the solid.

The ram is very heavy and designed for uniform rigidity throughout the entire length of stroke; is thoroughly braced by internal ribs and has long wide bearings with taper gib for taking up the wear. Cross-feed is variable and automatic with a range of .0114 to .250 with easy arrangement for any desired feed. The mechanism is substantial and simple, giving an exceptionally wide range. It readily adjusts itself to any elevation of the rail. Reverse of feeds is accomplished by simple manipulation of the knob shown, without stopping the machine. Rocker arm is made double section at the top, and this, with large opening through the column, permits a shaft 3½-in. diameter to be passed under the ram for key seating. Larger shafts may be key-seated by setting over table to allow the shaft to pass outside of column, using the head set on an angle.

All gears are cut from the solid with special cutters. Bevel gears are planed and are coarse pitch and wide face. Pinions in driving train are cut from bar steel. Easy access is provided to all working parts with convenient and effectual means for constant lubrication. All bearings are extra wide and scraped to surface plate. All running bearings are bushed to afford replenishing in case of wear. Bearing for driving pulley is massive and cast integral with column; is exceptionally long, extending well into the centre of cone, eliminating the necessity of an out-bored bearing for cone shaft. This bearing is bronze bushed. All shafts are of high carbon crucible steel, accurately ground. Points of danger are amply covered to prevent injury to the operator.



American Back Geared Crank Shaper.

You remember what Gen. Sherman said about war. His remark would have been equally applicable to the mind so tortured by business cares that it cannot forget them even on Sunday.

TURRET LATHE FOR SPECIAL WORK.

FOR finishing the interior and ends of small gasoline engine cylinders, Pratt & Whitney have placed on the market a very efficient and satisfactory turret lathe. The special head provided for this purpose is shown in Fig. 1. The other illustration shows the machine without the usual rod feeding and holding device. It is, instead, fitted with a special chuck for rigidly holding the cylinder and with turret and cross slide tools for boring the inside of the cylinder and for turning and facing a collar at one end. The work is gripped by means of two swinging clamps on the chuck. Each clamp operates against two fixed points, and also has two boring pins and a swinging member. The work, consequently, is supported on eight separate points while it is being machined. This avoids the necessity of clamping so tightly as to distort the casting, and also insures that the bore and the cylinder will be true when the work is removed from the chuck.

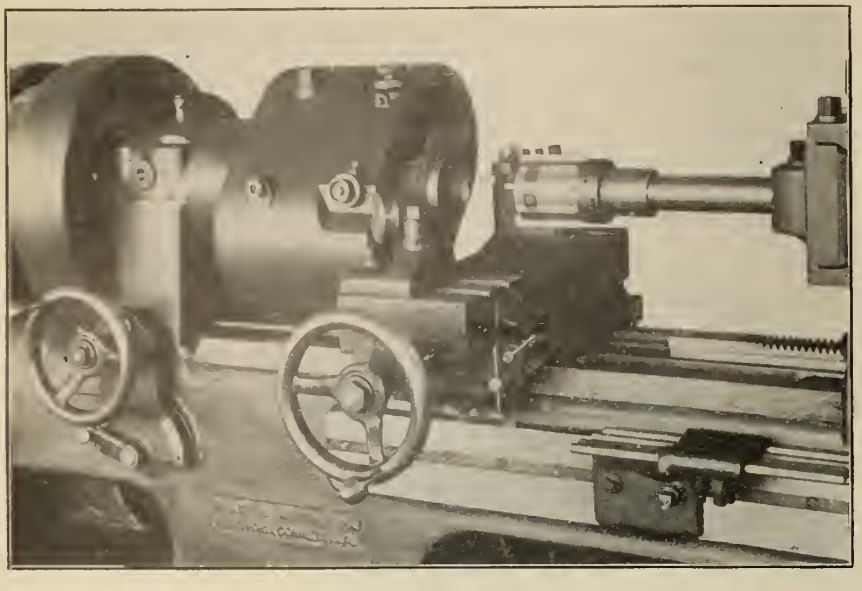


Fig 1 Special Head of Pratt & Whitney Turret Lathe.

The turret tools are for boring cylinders and consist of rigid boring bars with high speed cutting tools. An arm holding the cutter for turning the collar heretofore referred to, is fitted on the shank of one of the bars, and is clearly shown in the illustration. No detailed explanation of this feature is necessary.

The reamer for finishing the hole is allowed to float on its shank and is of the expansion type. The illustrations of the cross slide tools also are self-explanatory. It may be noted, however, that as both the turret slide and the cross slide have independent power feeds, both the boring and the cross slide tools have simultaneous action and effect considerable economy in time. The cylinder shown in the illustration has a diameter of 4 inches, and is 7 inches deep.

This lathe is particularly applicable to automobile manufacture. A large number are in use on this work and are giving excellent satisfaction. Where there is insufficient work to keep the machine constantly at work on castings, it is advisable to have it equipped with a rod feed and collet mechanism. This would permit rod work to be handled as well as the castings.

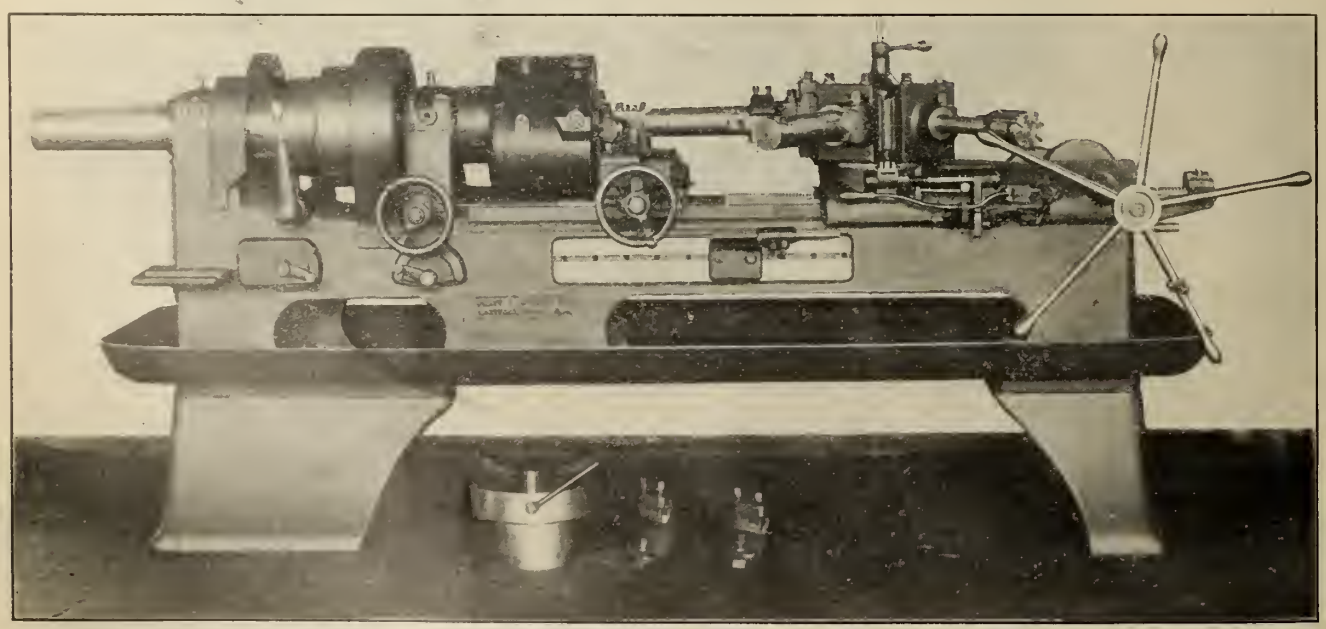

Fig 2 3 x 36 in. Pratt & Whitney Turret Lathe.

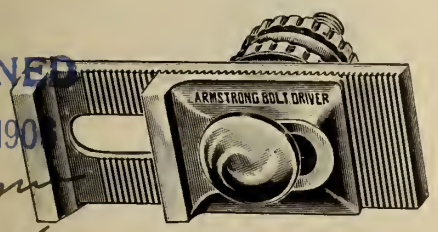
MECHANICAL SPARKER FOR GAS ENGINES.

A NEW type of spark generators for gas engines, which does away with the customary commutator and the magnetic vibrator, is described in a catalogue recently issued. The mechanical vibrator contains two platinum contacts. Even though the engine may be turning very slowly, no contact is made until the spring is released. All of these parts are very light, which allows for a quick release of the spring, and as the duration of contact can last no longer than the time taken for the release of the spring, and as the time

is always constant, no matter how low the intervals between each release, a quick "make and break" is always accomplished, making a spark of a constant size for all speeds of the engine.

ARMSTRONG BOLT DRIVER.

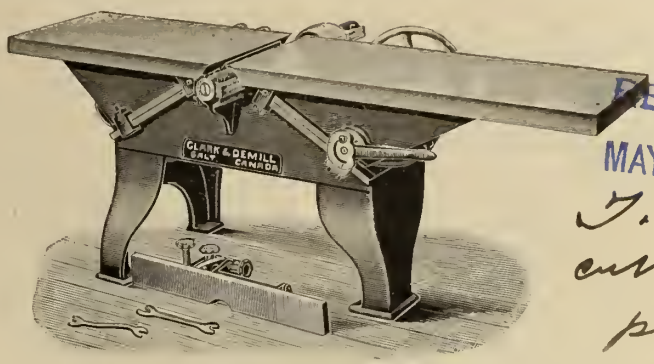
IN the two accompanying illustrations are shown a bolt driver recently placed on the market by Armstrong Bros. Tool Co., Chicago. Its particular use, and a field in which it will meet with a ready reception, is for turning and threading bolts in a lathe. There should be a good demand for a device of this sort. The views given show clearly the details of this holder as well as its method of application. As will be seen it is adaptable to square, flat or hexagon stock. By means of the extension washer between the driver and the face plate of the lathe the position of the driver can be adapted to centres of varying lengths. The driver is made in three sizes varying in capacity from two to four inches.



Armstrong Bolt Driver.

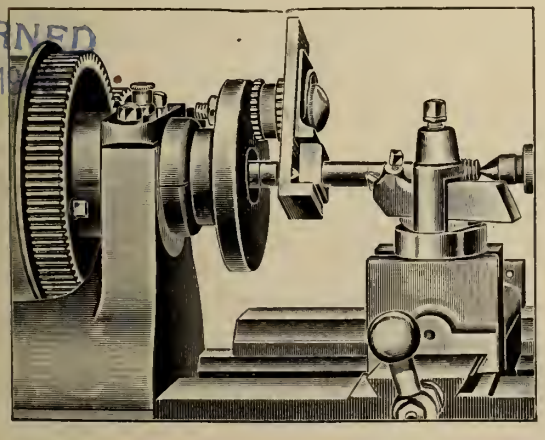
IMPROVED WOODWORKING MACHINES.

SOME of the recently designed woodworking machines, the product of Clark-Demill Co., Hespeler, are illustrated herewith. The improved pony planer is a strongly built machine for general use in box and furniture factories, planing mills, etc. The cylinder has large and long bearings, 1¾ in. x 6½ in.; is forged from a solid bar of high-grade steel; is driven from one side by patent anti-pneumatic double flange pulley, 5 in. x 5½ in. The hood in front of cylinder forms a chip breaker and pressure shoe and moves in a circle with the cylinder. It is so arranged that in taking ¼ in. cuts the hood will lift about 3-16 in. before the lumber reaches it, thus preventing a great deal of the strain on the hood, and at the same time holding the lumber firmly so as to prevent any roughness in planing. The steel scraper is attached to the delivering roll, which prevents it from gumming and marking the lumber. The shaving guards prevent shavings from getting beneath the smooth roll and imprinting the work — an important point in the purchase of a smoothing planer. Top rolls are solid, 3 in. in diameter and are strongly geared. Bottom rolls are 5 in. in diameter, giving a very strong feed. The table is 3 feet 3 in. long, and the screws for raising and lowering are square-threaded, passing through brass nuts, and move ⅛ in. to each turn of the handle. The handle for raising and lowering the same is convenient to the operator, as is also the indicator. A lock is provided so the table will not move when set to the thickness required. The countershaft when ordered is separate from machine, and can be placed underneath, above or on the floor, as may be desired.

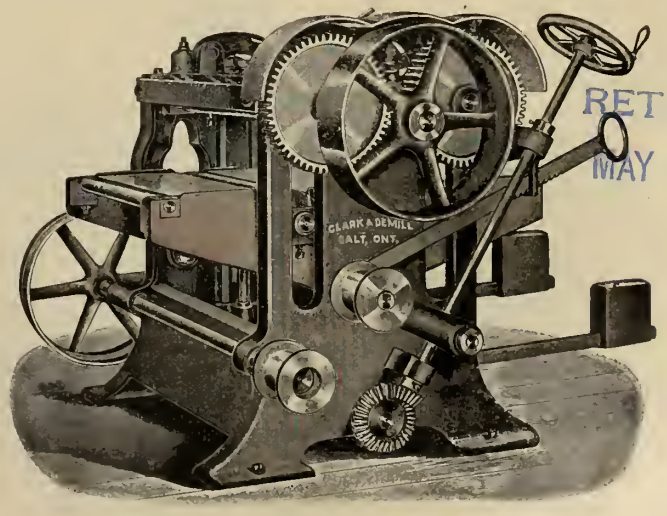


Perfection Buzz Planer and Jointer.

The other machine shown is a Perfection buzz planer and jointer, of which the frame and cylinder bearings are cast in one solid piece. It is extra heavy and strongly built, and has three points of bearing on the foundation so that it cannot be twisted by unevenness of foundation or floor. The tables are 7 ft. 3 in. long, and move on continuous inclined ways. An adjustable bevelled gauge is provided, secured to the rear or short table so as not to interfere with the working table. The eccentric under front or working table allows the table to tilt perfectly parallel from 0 to 1½ in. for hollow or glue jointed. This allows the back or short table to remain always set true to receive the work. In this machine there are no links or pin joints under the tables to get out of adjustment or wear slack. The machine having a three point bearing, it is impossible to strain or twist it by bolting down, or by floor settling, etc., and no projecting flange for the operator to tread upon. By means of the large hand wheel at right, the working table can be moved either to



Bolt Driver in Operation.



Clark-Demill Pony Planer.

or from the cutter-head without requiring the operator to change his position in the least.

STERLING POWER HACK SAWS.

ONE of the noteworthy features of the Sterling power hack saw, manufactured by the Diamond Saw & Stamping Works, Buffalo, N.Y., is the interposition of a train of reducing gears between the driving pulley and the crank shaft. By this means the pulley is allowed to run at a greater speed than in a direct-driven machine, so that a narrower belt can be used and still have ample driving power. To avoid the complications and difficulties frequently experienced with a clutch the machine is driven by the older method of tight and loose pulleys. The arrangement is such that after the work has been completely cut through the next return stroke of the saw automatically throws the belt from the tight to the loose pulley. The device has the advantage of greatly reducing the liability of breaking saw blades. The saw is fed in the usual way by its own weight, with the provision of means for adjusting which tends to avoid the buckling or breaking of the saw blade and adapts the saw to cutting of different materials between the extremes of soft steel and tool steel. The machine is made with all parts interchangeable, so that new parts may be readily substituted for ones that have been broken or worn out, making the machine easy to keep in repair.

The design of the machine as a whole is commendable for the effective distribution of metal to provide the greatest strength for the least weight. To obviate any likelihood of the shafts getting out of alignment or working loose the bearings of the driving shaft and crank shaft are cast on the bed.

NEW PIPE BENDING MACHINES.

THE accompanying illustration shows a machine lately perfected by Pedrick & Smith, Philadelphia, for bending pipe cold. Piping of steel, iron, brass, copper or other material can be bent cold up to and including 2 in. in diameter. The machine is also adaptable by means of special formers for bending light angles, flats and tee bars.

Page 41
W. S. E.

Improved Pipe Bender

The gearing is compound with a ratio of 25 to 1, thus giving the machine a powerful leverage. A boy can bend 2 in. pipe with little effort. The machine

To Canada
Cut Book 47
Page 41

Sterling Hack Saw.

is operated by a hand wheel consisting of four handles which, by means of the compound gearing, engages the face plate, to which are attached the bending quadrants. The pipe is held in the quadrant at the one end by means of a steel plate, while the resistance stud on the movable arm engages the other end. The various curvatures are obtained by adjusting the arm, which has a swing of three-quarters of a circle, supplemented by the movement of the resistance stud in the "T" slot of arm. The machine is mounted on a telescopic stand which can be raised or lowered to any suitable height; when the base is fastened the upper part swivels. A universal arm or section for the stand is furnished, so that if so desired the face plate can be placed in a horizontal position at any height from the floor. Quadrants are furnished with the machine for 1 in. pipe with a radius of 6 in., for 1¼ in. pipe with a radius of 9 in., for 1½ in. with a radius of 12 in., and for 2 in. pipe with a radius of 14 in. While these four quadrants are furnished with the machine, we find that the smaller sizes of pipe can be readily bent, and satisfactorily, in the larger size quadrants. In fact workmen will not take the time to change the quadrants unless they desire a smaller radius than the larger quadrant will give them.

SELF CONTROI

If you are tempted to be angry, pause a moment and still the rising activities. Deal in the same way with the tendency to be annoyed, resentful or depressed. Remember that if you spare yourself these useless expenditures of force, you husband and increase your energy.—Dresser.

Practical Questions and Answers

Horse-Power from Torque and Speed

Ques.—In the testing of an electric motor by brake test, you have the speed of the motor and the pressure of the brake arm upon the scales, besides electrical measurements of the input power. How can you find the horse-power output of the motor under these conditions of speed and input power?

Ans.—The length of the brake arm in feet multiplied by the pressure of the arm on the scales in pounds will give the torque in foot-pounds produced by the motor. Then if the speed of the motor be reckoned in revolutions per minute a convenient formula for finding the horse-power is:

$$H.P. = \frac{T \times N}{6300}, \text{ where}$$

H.P. = horse power,
T = torque in foot pounds; and
N = revolutions per minute.

Advantages of Compound Air Compressors.

Ques.—What are the advantages of compressing air in two, three or four stages in an air compressor?

Ans.—As air is compressed in a cylinder its temperature rapidly rises. If during the stroke no heat is removed from the air in the cylinder the air is said to be compressed adiabatically; or if during the compression the heat as it is generated is removed by some means and the air in the cylinder thus kept at the same temperature throughout the stroke, the compression is said to be isothermal. If the air is compressed adiabatically it enters the receiver at a much higher temperature than the surrounding atmosphere, and as it cools down to the atmospheric temperature, the pressure takes a corresponding drop; on the other hand, if compressed isothermally the air upon entering the receiver is at atmospheric temperature and consequently there is no change in either temperature or pressure. Thus it is evident that to obtain a certain final pressure in the receiver in the adiabatic compression it would be necessary to compress to a somewhat higher pressure than that of the receiver, so that when the air cooled down the pressure would not drop below that required in the receiver. Raising the air to this higher pressure would mean an extra amount of work done.

There are two methods adopted to bring the compression as near isothermal as possible; one of these is by water-jacketing the cylinder, and the other is to compress the air in two, three or four stages, cooling the air to atmospheric temperature, or as near to it as possible, in intercoolers between each compression. Although water-jacketing is a very common practice, it is not as effective a method of cooling as one might wish because air is a poor conductor of heat and during the stroke there is not time for the water to absorb much heat from the air. Experiments conducted on single cylinder compressors, with water-jacket, and with compound compressors, also water-jacketed, have shown over one hundred per cent. greater saving in lost power for the compound compressors than for the single-cylinder compressor.

These foregoing facts might be expressed mathematically somewhat as follows:

The equation for the isothermal compression curve is $p\,v$ = constant, or $p^1 = p^0 \left(\frac{v^0}{v^1}\right)$, while the equation for the adiabatic compression curve is $p\,v$ = constant $^{1.405}$, or $p^1 = p^0 \left(\frac{v^0}{v^1}\right)^{1.405}$

The amount of work necessary for compression is least for the isothermal and greatest for the adiabatic. The adiabatic curve can be made to approach the isothermal curve by decreasing the exponent 1.405. With a single-cylinder compressor with an efficient water-jacket this exponent can be reduced to 1.25, while with the compound compressor with water-jacketed cylinders and efficient intercooling devices the exponent can be reduced to 1.15.

Size of Steam Supply Pipe.

Ques.—It is required to supply a steam engine with steam from a boiler. The steam consumption of the engine is known. From that how would you determine the size of steam pipe required?

Ans.—A formula commonly used for this purpose is as follows:

$$d = 0.5374 \sqrt[5]{\frac{Q^2 L}{H}}, \text{ where}$$

d = diameter in ins. of steam pipe required.
Q = quantity of steam in cubic feet per min.
L = length of steam pipe in feet; and
H = height in feet of a column of steam, of the pressure of the steam at the entrance, which would produce a pressure equal to the difference of pressures at the two ends of pipe.

The value of H can be found from the formula:

$$H = \frac{144\,(p^1 - p'')}{w}, \text{ where}$$

p^1 = pressure in pounds per sq. in. at boiler end of pipe;
p'' = pressure in pounds per sq. in. at engine end of pipe; and
W = weight per cubic feet of steam at pressure p^1.

Thus we get formula:

$$d = 0.5374 \sqrt[5]{\frac{Q^2 L}{\frac{144(p^1 - p'')}{w}}}, \text{ or}$$

$$d = 0.5374 \sqrt[5]{\frac{Q^2 L w}{144(p^1 - p'')}}$$

In this formula Q is known or can be found from known quantities, i.e., steam consumption of engine, L is known, P is known (boiler pressure), and w can be found in any table of steam properties. The two unknown quantities are d and $(p^1 - p'')$, and from the formula a relation between them is obtained. The pressure required at the engine can be decided upon, and will practically have to be decided upon before Q can be known accurately. Hence the value of d is determined.

As a check on this result the velocity of the steam through the pipe of diameter d might be found from formula:

$$V = \frac{12Q}{2\pi d}, \text{ where}$$

V = velocity in feet per min.

This velocity for stationary engines should not exceed 100 feet per minute.

Suction Pipe for Boiler Feed Pump.

Ques.—How can the size of a suction pipe necessary for a boiler feed pump be determined?

Ans.—If the speed of the piston is known or can be determined, and if the length of the suction pipe will not have to be more than 24 feet, the following emperical formula may be used, which is based on the assumption that the velocity of the water through the suction pipe must not exceed 200 feet per minute, for fear of excessive frictional loss, and that there are not more than two elbows in the pipe: Size of pipe is given by 7-10 diameter of pump cylinder multiplied by 1-100 of piston speed in feet per minute.

For moderate wear the piston speed should not exceed 100 feet per minute.

INDUSTRIAL PROGRESS

MACHINERY AND MANUFACTURING NEWS would be pleased to receive from any authoritative source industrial news of any sort, the formation or incorporation of companies, establishment or enlargement of mills, factories or foundries, railway or mining news, etc. All such correspondence will be treated as confidential when desired.

A. M. McGill has re-opened the foundry at Chatsworth, Ont.

F. B. Moffat, of Enderby, purposes erecting a flour mill at Vancouver.

The Stuart Machinery Co., of Winnipeg, will erect shops at a cost of $10,000.

Edmonton has decided to take over, own and operate its own street car lines.

The Bulwell Coal Co., of Calgary, has started operations near Lethbridge, Alta.

The Peterborough Lock Co. have paid a dividend of 6 per cent. for the past year.

The International Harvester Company will erect a warehouse at Regina this year.

The directors of the Winnipeg General Hospital have decided to erect a nurses' home.

The amount of bounty paid on iron and steel for the past calendar year was $1,900,206.

The Raymond Mill & Elevator Company will build a $25,000 mill at Magrath, Alta.

T. Long & Bro. will erect a large elevator and cold storage warehouse at Collingwood.

Geo. Esterbrook, of Tweed, Ont., expects to erect a large flour mill at Vancouver, B.C.

The Canadian Otis Elevator Works, of Hamilton, will build a $4,000 addition to their works.

Heard & Co's tool works, of St. Thomas, report a very busy season, particularly in rakes.

Tenders are asked for the erection of a brick Methodist Church at Markdale, to be 70 by 72 feet.

A three-storey carriage factory will be erected at Fredericton, N.B. E. A. Morgan is interested.

A joint stock company is being formed at Lansdowne, Ont., to erect a large harness factory there.

The Roberts Heating and Ventilating Co., Minneapolis, will build a $20,000 warehouse at Winnipeg.

The Cockshutt Plow Company purpose building a large warehouse in Arcola, Man., next Spring.

The factory of the Canada Glue Co., Brantford, is about completed and will soon be running full time.

A new smelter is proposed to be established at Cobalt, by the proprietors of the Timmins Mine.

The town of Rainy Lake passed a by-law to raise $35,000 to install a waterworks and sewage system.

Over 100 men are at work on the Canadian Metal Company's works at Frank, Alberta, and smelting is to commence in about a month.

The Calgary Lime & Cement Company are building new lime kilns and otherwise extending their plant.

Building in Haileybury, Temiskaming district, has been going on all Winter. The town is growing rapidly.

J. Trussler, of Owen Sound, is at the head of a cement brick company which will build a factory in Berlin.

The Sandstone Brick Co. have bought ten acres southwest of Peterboro for the new plant it has just ordered.

The Toronto Bolt & Forging Company will erect a 400-foot brick extension to their plant at Swansea.

R. H. Grimstead, of Minneapolis, purposes building a factory in Winnipeg for the manufacture of steel harrows.

Price Bros. & Company are reconstructing their mill at Metabetchouan, Que., which was destroyed by fire.

The Y.M.C.A. will shortly erect a building at the corner of McRoberts and St. Clair avenues, Toronto Junction.

It is rumored that the C.P.R. intends to push the branch line which runs from Mattawa on to Cobalt this Summer.

Joseph Cameron is erecting a shingle mill on some limits he holds near the Port Moody road in Coquitlam, B.C.

J. E. Beliveau will erect a three-storey, forty-room hotel at Brantford, corner of First avenue and 22nd street.

The Peterboro' Board of Education are asking for $30,000 to build a new public school in the south end of the city.

The Dominion Coal Co's output for January, 1906, was 231,606 tons, an increase of 70,000 tons over January, 1905.

3,280 permits for 4,030 buildings, of an aggregate value of nearly $11,000,000, were issued in Winnipeg last year.

The manufacturers' committee of London, Ont., will ask the city council for $1,000 for the purpose of advertising the city.

The Kingston Yacht Club, Kingston, ask tenders for removal of their old club house and the erection of a new one.

Ontario Wind Engine & Pump Co., Toronto, are to build a three-storey and basement brick factory, to cost $8,000.

The Richelieu & Ontario Navigation Company will build three new passenger steamers at a cost of about a million dollars.

The Canada Jute Company and the Dominion Bag Company have amalgamated and will build a large factory in Winnipeg.

Over one thousand prospectors' licenses have already been taken out this year from the Government office at Haileybury.

Dresden ratepayers will vote on a by-law to provide $25,000 to assist A. H. Turner, of Toronto, in building a twine factory there.

The production of carborundum in the United States in 1905 is estimated at 5,596,280 pounds, against 7,061,380 pounds in 1904.

Compton & Montgomery are erecting a new store building at Daysland, Alta. A new hotel, the Argus, is also building a large annex.

Winder Bros., of Berlin, announce their intention of building a three-storey and basement furniture factory, to cost $25,000.

The Farewell Foundry Company, Berlin, will soon have their foundry running. Their output will chiefly be iron pipe and fittings.

The American Locomotive Works, Montreal, are delivering sixteen high-class passenger engines to the Intercolonial Railway.

The Dominion Sewer Pipe Company are running their works to the fullest extent in order to handle their large northwest business.

E. W. Hewson, of Amherst, N.S., will erect a four-storey building for business purposes in Vancouver, costing between $35,000 and $40,000.

Tenders are asked for the erection of a new post office building at Regina. February 23 is the date of time limit for receiving tenders.

Woodstock may have another industry which will manufacture a new patent screen, the rights of which are controlled by local men.

M. Fisher, Sons & Company, purpose erecting a seven-storey warehouse and office building on the lower part of Victoria square, Montreal.

The Canadian Rand Drill Co., Sherbrooke, Que., will build extensive additions to their works, including the erection of a new foundry.

The Sydney Steel Works report an unusually good month for January, the total shipments during the month being upwards of 17,700 tons.

Leon Vanhavrebeve, representing the Belgium Packing Company, is in Lethbridge negotiating for the establishment of a packing house there.

Gatineau Point will grant exemption for 25 years to a company about to build a sash and door factory there. Work will be commenced at once.

Samples of copper ore from Cloud Bay, Ont., have assayed high values. The vein from which the ore was taken is 23 feet wide in places.

It is reported that the Canadian General Electric Company will erect a plant for the manufacture of mining machinery at Rossland, B.C.

The Imperial Wire & Nail Works, of Collingwood, will make extensive additions to their plant, as will also the Collingwood Furniture Co.

The Michigan Central shops, of St.

Thomas, have been very busy of late, but the Pere Marquette shops have been rather slacker than usual.

Tenders will be asked shortly for the erection of a new barracks at Toronto, for the permanent corps. About 400 men will be accommodated.

The International Atcheson Graphite Co's factory at Niagara Falls is now in operation. This factory has ten electric furnaces costing $35,000.

The Kenora Board of Trade will ask the town council to secure surveys and estimates for an electric railway between Kenora and Keewatin.

The winding up of the Robinson & Turner Co., of Toronto Junction, ladder manufacturers, shows no visible assets, and liabilities of over $5,000.

The Canadian Pacific Railway Company will build terminals at Lethbridge, Alta., including a ten-stall roundhouse, freight shed and repair shops.

A by-law to grant a bonus of $10,000 to Brunet & Couson, to establish a shoe factory at Maisoneuve, Que., will be submitted to the ratepayers.

The Canadian Military Institute, Toronto, have purchased property on Simcoe street, and will erect a new club house at a cost of about $15,000.

The McDonald, Dunlop Company, of Calgary, are erecting a three-storey brick warehouse, 130 feet long by 25 feet wide, which will cost $12,000.

The Imperial Steel & Wire Company, Collingwood, are to build a wire fence plant. Their nail mill is working on large orders from wholesale houses.

The Anthony Wire Fence Co. are installing machinery in the factory they have leased at Windsor, and will employ 10 or 15 hands in a short time.

The Amherst Foundry Company, Amherst, N.S., have ordered from the Smart-Turner Machine Company, Hamilton, a single beam traveling crane.

The Intercolonial Railway Co. have delivered their new 80-pound rails from Sussex to St. John, N.B., which will replace the 50-pound rails now in use.

The Norris Safe & Lock Company will build a five-storey block in Vancouver. The company has recently completed a six-storey building in Seattle.

The Brandon Brewing Company, who had their factory burned on Christmas Day, will rebuild on a larger scale than ever. The new building will cost $75,000.

The Midland Construction Company will have two large steel scows constructed, to be used in connection with their new dredge, which is now being built.

The shareholders of the Canadian Pacific Railway Co. will be asked to consider the increasing of the company's capital stock from $110,000,000 to $150,000,000.

The Garr-Scott Threshing Machine Company are negotiating with Regina with a view to erecting a large warehouse there, similar to the one in Winnipeg.

The Grand Trunk Railway Co. have authorized the expenditure of three and a half millions in rolling stock in order to handle the coming season's wheat crop.

The Canadian Pacific Railway Company will build a large storehouse in Montreal, in connection with its freight sheds, for the convenience of the merchants.

The Metal Shingle & Siding Co., Preston, have secured the contract for the metal roofing of the new field mechanics' building at the Guelph Agricultural College.

Canadian railways have already placed orders for 200,000 tons of rails for 1906. These rails will be made in Canada, at Sydney, C.B., and Sault Ste Marie, Ont.

Mr. Frederic Nicholls, president of the Niagara and St. Catharines Railway & Navigation Co., announces that he will put a new boat on the Port Dalhousie line for 1907.

The city of Vancouver issued building permits in January, 1906, representing $177,920. This exceeded December last by $27,000. A busy year in building is expected there.

The shareholders of the Brantford Screw Company will be asked to increase the capital stock in order to put their plant in shape to handle their growing business.

It is announced that the Grand Trunk Railway Company will build a large bonded warehouse this year on the property expropriated for the new Union Station in Toronto.

It is announced that the Grand Trunk will spend a million dollars in London on raising the tracks, constructing subways, and the erection of a new station building.

The Fraser River Lumber Company, of New Westminster, B.C., will build a two-storey saw mill 34 by 84 feet. The place will be equipped with up-to-date machinery throughout.

E. D. Brand, who has disposed of his interest in the Berlin Electrical Company, is at the head of a new company who will shortly begin the manufacture of dry batteries in Berlin.

Brantford may have an electrical supplies factory. An outside company have had a representative there with this in view, and the city council have promised to assist the new industry.

The Monarch Brass Works, of Port Colborne, struck a good flow of natural gas at a depth of 1,000 feet in their gas well. Their whole plant will now be run by gas from their own well.

The Central South African Railway will shortly call for tenders for supplying Douglas fir. Copies of specifications may be had from the Superintendent of Commercial Agencies, Ottawa.

Messrs. Geo. Schlee, D. B. Detwiler and M. B. Shantz will build a button factory in Berlin, employing between 50 and 60 hands. A sandpaper factory is also spoken of for this town.

The Board of Education for Toronto have made large appropriations for the erection of new schools and collegiate institutes, and for the enlargement of many of the present buildings.

The Niagara, St. Catharines & Toronto Railway Co. will apply to parliament for permission to extend its line from Niagara Falls to Brantford, also from Thorold to Niagara-on-the-Lake.

After expending $25,000 the Western Gas & Oil Company has struck gas at Edmonton at a depth of 1,450 feet. The pressure of the flow is 250 pounds, and it produces a clear white light.

The Western Counties Power Company have acquired the plant of the Brantford Electric & Operating Company and will operate in that city. They intend to bring Niagara power to Brantford.

W. H. Banfield & Son, Toronto, are meeting with unqualified success in the placing of their drop hammers and power presses on the Canadian market, having received numerous orders lately.

The bursting of a boiler in the Stanfold block, Montreal, recently partially wrecked that building, but, fortunately, no one was injured, although there were many people in the building at the time.

The Granby smelter, at the Boundary Mines, in the Kootenay district, produced $2,000,000 lbs. of copper last month. The Granby smelter is the largest copper reduction works in Canada.

Montreal capitalists are interested in the peat, gas and coal company recently organized at Portland, Maine. T. P. Gelinas, of Montreal, is president, and J. D. Oligny, of the same city, treasurer.

Assessment Commissioner Forman states that a large oil industry will be erected on Ashbridge's Marsh, Toronto. They will commence with about 25 men and an immediate expenditure of $20,000.

The contract for railroad construction near Manila has recently been given, amounting to $16,000,000, to the J. G. White Co., of New York, of which the Canadian White Co., of Montreal, is a branch.

The Canada Flax & Cordage Co. will establish a twine factory at St. Mary's to cost $60,000 and undertake to employ 50 hands on condition that the town guarantee bonds to the amount of $25,000.

The citizens of Midland, have hopes of that town becoming the lake terminus of the Grand Trunk Pacific railway. The G.T.P. have purchased considerable yard room and water frontage there for this purpose.

After April 1 next the Toronto Street Railway Co. will pay a dividend of six per cent. per annum instead of five per cent. In percentage of earnings, rentals and taxes, the city received during 1905 $405,638.89.

The Maritime stove manufacturers are having trouble in their provincial association on account of one concern in Sackville employing striking employes of another factory, which is contrary to agreement.

The Lyons Electric Company, of Brantford are asking that city for a ten years' franchise for commercial lighting. They offer to supply a current at a flat

rate of 5 cents for a 16-candle-power lamp a week.

Assessment Commissioner Foreman, of Toronto, has been negotiating with representatives of a large firm from the State of Indiana, now employing 400 hands, who wish to locate a branch factory in Canada.

The Granby Company have acquired the Pathfinder Mine, and in the early Spring will pen up and work the property. The Pathfinder Mine is a gold-copper proposition, 12 miles from Grand Forks, N.D.

The Allis-Chalmers Company are putting in a large saw mill plant on the west coast of Vancouver Island, at Mosquito Harbor. The machinery has just arrived from Milwaukee and is up-to-date in every way.

The Ever-Ready Fire Extinguisher Co. have secured control of a new fire fighting appliance which contains a combination of carbonic acid gas and water. They will manufacture these articles at Brandon.

Building operations in Langham, Sask., will be extensive this year. This time last year there was only one shack there, and now every business is carried on there except banking. Several buildings are already started.

The sub-station of the Huronian Power Company, at Copper Cliff, is nearing completion. Power will be transmitted to Copper Cliff in two weeks. About $250,000 has been expended on the power house and equipment.

The Canadian Northern are preparing to commence work in earnest in the Spring on their long-talked-of line to Hudson Bay. A party of surveyors have been working all Fall and Winter on the proposed line.

The Dominion Coal Company have under consideration a scheme to build homes for their 5,000 miners. The plan is to build houses suitable to their ability to purchase, and allow eight years in which to pay for them.

A new smelting furnace has been invented by Mr. Blanchard, of Spokane. It is a double blast furnace, and the chief claims for it are rapidity in smelting and a saving of fuel. Raw coal is used instead of coke.

Immense quantities of steel rails are being shipped to Fort William and stored there awaiting shipment further west. Some of this is for the Seattle & International Railway line, and some for Cowley and Laggan, B.C.

The Wolverine Reed Co., of Detroit, have closed their plant there and are moving to Walkerville, having leased the building formerly occupied by the match company. The reed works will employ from 50 to 60 hands.

The Toronto Railway Company are building a number of cars for Winnipeg, and will also build more new ones for the Toronto service. The company have also been negotiating for about 5,000 tons of steel rails for Toronto.

Wilson B. Bechtel, of Bechtel Bros., brick manufacturers, of Waterloo, has left the firm, and purposes erecting a modern brick-making plant. He will invest between $12,000 and $15,000, and will employ about fifteen hands.

The Dominion Coal Company's earnings for 1905 were $1,573,000, as compared with $1,602,000 for 1904. The decrease is owing to an unremunerative contract at present existing with the Dominion Iron & Steel Company.

Williams & Wilson, of Montreal, state that the demand for carborundum wheels is unprecedented and that more orders have been filled for these wheels during the past few months than were called for of other abrasives for several years.

At the annual meeting of the Ottawa Electric Railway Co., Thomas Ahearn was re-elected president. The gross receipts of the road were $449,000, and the net profits of the year $143,000. A dividend of 10 per cent. was declared.

The stone quarries owned by the Western Fuel Company on Newcastle Island, near Nanaimo, B.C., which have been idle for some time, have been reopened under the management of the Northwestern Construction Company.

A six-storey hotel, to cater to the best trade, will be built in Vancouver by the Marquis de Biddlescope, on the corner of Cordova and Seymour streets. Clark & Stewart, wholesalers, will also build shortly, on the opposite corner.

Since the death of Walter Grose, of Montreal, the Nicholson File Agency, held by that firm, has been discontinued. The Canadian business will now be conducted from Port Hope, with Mr. Chas. S. Archibald as Canadian representative.

R. E. T. Pringle & Co., Limited, have been granted permission to erect a large electrical factory on Delisle street, St. Henri. The new structure is to be a most complete one and will be thoroughly equipped with labor-saving machinery.

The Lock Safety Pin Company, of St. Louis, are negotiating with Smith's Falls with a view to establishing a plant there for the manufacturing of the Lox safety pins, hair pins, hooks and eyes, etc., which at present are all imported.

H. J. McNeill, of Brandon, president of the Great Northern Manufacturing Company, has sold the invention known as the threshing machine belt guide and shifter, with all rights, to S. S. Graham, of Fargo, and J. C. Foster, of Hope, N.D.

The International Railway car barns at Niagara Falls have been destroyed by fire, the loss amounting to $125,000. It is reported that the company may move its division headquarters to Niagara Falls, N.Y. Thirty cars were destroyed with the barns.

The Canadian Copper Company is surveying a right of way from Copper Cliff to Creighton to convey power to the property there. The operation of the entire plant by electricity is proposed, and plans are now being prepared with this end in view.

The Canadian Pacific Railway Company have given an order to the Dominion Car Company for 200 steel coal cars to cost upwards of a million and a half. They were not able to make them at their own shops in Maisonneuve owing to pressure of work.

An American company of capitalists have purchased a tract of iron land at Sheep Rock Lake, near Fort Frances, from W. A. Preston, of Fort Frances. The purchasers will immediately expend $50,000 in exposing the ore and getting some on the market.

The City Council of Hamilton, in opening the tenders for the cement supply, were somewhat surprised at the increase in price asked by the different dealers. The uncertain condition of the coal situation has had a tendency to make the cement men cautious.

The Canada Foundry Company, of Toronto, have made arrangements for the erection of a derrick at Fredericton, N.B., to remove the steel spans from the cars which will arrive in February. These spans are for the superstructure of the Fredericton highway bridge.

Tests made by the Canadian Northern Railway with Edmonton coal show that a train hauling 700 tons of freight from Edmonton to Vermillion burned seven and a half tons of this coal, as compared with eight tons of Crow's Nest coal used under the same conditions.

Allis-Chalmers-Bullock, Limited, of Montreal, have removed their sales office for the Maritime Provinces from Halifax to New Glasgow. This is considered a more central locality for the great steel, iron and coal industries with which a large portion of their business is done.

The Dominion Coal Company have commenced the erection of a new foundry at Glace Bay, N.S. A machinery storage house, 30 x 110, is also being erected, and further work will be carried on in the near future in the construction of a machine shop and the sinking of a well.

Alex. Morison, of Bay City, patentee of a process for manufacturing binder twine from flax cordage, is in Sarnia regarding the erection of a factory there. It is claimed for Mr. Morison's process that it will produce a superior binder twine at much less than the present prices.

Mackenzie & Mann have given a contract to J. P. Mullarkey and M. J. O'Brien to build 100 miles extension to the Great Northern Railway in Quebec. Eighty miles will run from Garneau Junction to Quebec City, and twenty miles from Montfort Junction to St. Jerome.

The Window Glass Machine Company of Canada have entered into agreement with the town of Cayuga, which will be voted on March 2. Representatives of the Imperial Plaster Company, of Toronto, have also been to Cayuga with a view to opening up the plaster deposits there.

One of the largest orders for machine tools ever given at one time by a single company was placed recently by the Allis-Chalmers Co., of Milwaukee, the price for these being $550,000. They include forty-two machine tools of extra heavy pattern, designed especially for the use of high speed steels.

The Manitoba Iron Works purpose erecting a large boiler shop and structural iron working department, and to

facilitate the handling of heavy iron required for this work, have applied to the Winnipeg City Council for the privilege of double tracking their spur across Henry avenue.

H. W. Petrie, of Toronto, has opened a branch at the corner of St. James and Little St. Antoine streets, Montreal, where a good line of machinery will be kept in stock. Mr. A. W. Royan, who formerly represented John Bertram & Sons, Limited, in Montreal, will have charge of the branch.

Vancouver men—Geo. Martin, Wm. Shannon and W. H. Higgins—will erect iron and steel furnaces and mills at Eburne, B.C., where they will treat the magnetic ore deposits by electrical process. Lead and wooden pipe factories are also planned. English capitalists are interested in the scheme.

Despite the troubles amongst the directors of the National Portland Cement Company, at Durham, the stock of that concern is being quoted at higher figures. Meetings of the shareholders are being held at various centres and proxies secured in preparation for the coming annual meeting of the company.

The Robb Engineering Co. have recently received an order from the J. R. Booth Co., Ottawa, for one 20 x 36 inch Robb-Armstrong Corliss engine; two 22 x 36 inch Robb-Armstrong Corliss engines, and three 14 x 24 inch Robb-Armstrong Corliss engines. The above engines are for the paper mills at Ottawa.

The Hamilton Cataract Power, Light & Traction Company have decided to open the radial extension from Burlington to Oakville on May 1. Arrangements were made to double-track the radial from Hamilton to the canal early in the Spring. A dividend of five and a half per cent. was declared for the past year.

The recent inquiry into the congestion of the grain traffic in Western Ontario and at Georgian Bay points will result in an increase in the rolling stock of the Grand Trunk Railway Co. It was announced that the Grand Trunk Railway Co. would put on 5,000 new freight cars to satisfy the demands of the grain traffic.

The Allan Steamship Company will ask the Government to establish a system of telephonic and telegraphic communication on the St. Lawrence route to Montreal. They say that during the bush fire season smoke hangs heavily over the river, which, with the fogs they sometimes have, renders river traffic hazardous.

A valuable deposit of graphite has been found at French Vale, Cape Breton, by Mr. Neil L. Campbell. At a depth of 25 feet a 13-foot seam was discovered, samples of which on analysis were found to contain 75 per cent. of graphite. It is within four miles of the I.C.R. line, and six miles from Bras d'Or Lake.

The Williams Co., shoe manufacturers, have closed their factory in Galt, and will move the machinery to Brampton and merge with another business there. Under an agreement with the town they occupied an $80,000 building bought by the town to encourage the industry. The premises are already applied for by other concerns.

An evidence of the briskness of Canadian trade in the machinery and power and transmission development is shown in the plant of the Dodge Mfg. Co., Toronto, where the machine shop has been running over time for some weeks past, and where to keep up with a growing business additional machine tools are being installed.

A phenomenally rich discovery of copper has been made near Dean Lake Station, on the Soo branch of the C.P.R. The ore is found in a soft slate formation, which renders it easy to take out, and runs 12 per cent. copper, one large sample assaying 22½ per cent. copper. The lead has been traced for three-quarters of a mile.

A million dollar contract was given by the Montreal Street Railway Company for a new power house to be completed this year. The company has also let a contract for 6,000 tons of steel rails to lay 50 miles of track. No Canadian companies making "T" rails, the contract went to the United States Steel Corporation.

A company has been formed in Perth to develop a new industry in mica, known as the "thin splitting" process. In the vicinity of Perth there are still to be immense quantities of refuse or small mica, which is used in this work. A factory has been opened in the old bolt works and employment will be given to about ninety girls.

Among the recent sales by Allis-Chalmers-Bullock, Limited, Montreal, were thirty of the latest improved type coal cutters to the Dominion Coal Co., Glace Bay, C.B.; two compound steam-driven air compressors to the Acadia Coal Co., Stellarton, N.S., and a 425 k.w. alternating current generator for the corporation of Parry Sound.

Further experiments of Dr. Heroult at the Soo have demonstrated that pig iron can be produced by the electric process from red hematite at less than $10 per ton. This is significant in view of the fact that only a few days ago a leading steel manufacturer declared that it cost from $14 to $15 to produce pig iron by the old process.

The Canadian Shipbuilding Company will build for the St. Lawrence & Chicago Navigation Company one of the largest fresh water vessels afloat. It is expected she will be ready to go into commission in the Spring of 1907, and will be in the 10,000 ton class between 450 and 500 feet in length, although as yet the dimensions are not given out.

The Boundary Iron Works, Grand Forks, B.C., has declared its first dividend, which will be five per cent., payable on March 1. The business of this foundry has grown enormously, and it is expected it will do at least a $50,000 business during 1906. The machine shops of the Ketter Valley Line Railway have been removed to this foundry.

The Steger Sand Lime Brick Company, of Vancouver, will put on the market a new brick or building stone made from Britannia tailings. The brick will consist of fine particles of quartz bound together by lime in the proportion of five per cent. It is claimed for it that it will withstand nearly four times as much weight as the ordinary brick.

It is reported that Mackenzie & Mann will build a $5,000,000 smelting industry in the Ashbridge Bay district, Toronto. They hold an option on a valuable tract of iron ore land just outside Hutton, Ont. This company have a great deal of ore property, and the object of this smelter in Toronto is to have an outlet convenient to the Great Lakes.

The new smelter at Copper Cliff, erected for the treatment of cobalt ores from the mines in the Sudbury district of Ontario, has been successfully installed. The smelter has a capacity of 10 tons daily and is being operated as a custom smelter for the treatment of all precious metal bearing ores. The cost of erection was approximately $100,000.

Tenders have been called for the building of one of the most important sections of the Grand Trunk Pacific, from Touchwood Hills to Edmonton. Among those who tendered were Foley Bros. & Larson, J. McArthur, the Canadian White Company, McDonald, McMillan & Co., and Johnson & Sons. This section of the Grand Trunk Pacific is 450 miles in length.

At the coming session of the Ontario Legislature the Minister of Mines will introduce legislation with a view to having all the nickel ore mined in Ontario converted into marketable nickel before leaving Canada. Canada supplies 60 per cent. of the nickel of the world, but at present the ore is converted into the finished product in the States, and sold as American nickel.

The annual steel production of the United States is the largest in the world, amounting to fifteen million tons. Germany comes second with eight million tons, and England third with five millions. The 450 steel works in the States represent an investment of over $442,000,000, and pay $102,000,000 annually in wages. These figures represent the crude production only.

The Montreal Copper Refining Company, the only company refining copper in Canada, offer their stock for sale. Before the formation of this company all Canadian copper ore was shipped to the United States to be refined, and then re-shipped back to Canadian users. Besides supplying the home market to some extent, the Montreal refinery also export their product to Great Britain and Germany.

Frederiek Nicholls, of the Electrical Development Company, has twice absented from the Royal Commission on hydro-electric power, although subpoenas have been served upon him. He feels that in giving information he would be guilty of a breach of faith with the shareholders, and wanted the permission of the president Sir Henry Pellatt, who is abroad, before he would give testimony.

Some iron and steel manufacturers are not inclined to agree with Dr. Heroult, the French expert, who has been

conducting experiments in the reduction of ore by electricity, and who states that pig iron can be produced for $10 a ton. Montreal steel men say Dr. Heroult's basis for calculating cost in this electrical process is an erroneous one, and would not bear the test of practical manufacture.

The aggregate value of the contracts for the two sections of the National Transcontinental Railway for which tenders are asked will be from twelve to fourteen million dollars. The new syndicate, headed by W. J. Poupore, of Montreal, will be a strong rival to Foley Bros. & Larson for this contract. This latter firm have at present the contract of double tracking the C.P.R. from Port Arthur to Winnipeg.

The Allis-Chalmers-Bullock, Limited, Montreal, recently received an order from the Canadian Forty Mile Gold Dredging Co., of Toronto, Canada, for a special gold dredge equipped complete with 5 1-3 cu. ft. buckets. The contract covers the entire machinery equipment complete, ready for operation, including electric light plant, two boilers, 100 H.P. each, engines, pumps, etc. The dredge will be ready for use early in May.

The Lake Superior Corporation will erect two new open hearth blast furnaces at the Soo, which will increase their steel output by one quarter, at a cost of about $250,000. The company have applied to the Government for a rebate of the duty on coal used for making coke, and if this is granted they will also construct at least 50 coke ovens. These improvements, when completed, will require about 500 more men.

The Whelpley Skate Company, of Greenwich, is asking concessions from Fredericton, N.B., with a view to going there to manufacture. The company ask for a free site or nominal rental, exemption from taxation, free water and a loan of $5,000. In return the Whelpley concern will erect a $20,000 plant that will have an annual output of $30,000, and for the first year will employ 25 men. The Whelpley skates are well known in Canada.

The Smart-Turner Machine Co., of Hamilton, are installing their automatic feed pumps and receivers, and their duplex pumps in many localities. Recent orders for these include E. Leonard & Sons, London; the Belgo-Canadian Pulp & Paper Co., Standard Soap Co., Calgary; Hamilton Cataract Power, Light & Traction Co., Hamilton; Wilson Steel Works, Toronto; Geo. Frid & Co.; the London Fence Machine Co., Murray's free stone quarries.

Hon. Henry Cecil, mining engineer and mine owner, says that it is the policy of those who are interested with him in British Columbia copper enterprises to divert the export of copper so that it will go through British, instead of American, channels. To this end they have in view the establishing of a large copper refinery at Montreal. A small copper refinery already exists there, and it might form the nucleus of something greater to be.

The National Malleable Castings Company, of Cleveland, has brought suit against the Smith's Falls Malleable Castings Company for $50,000, for breach of contract. The plaintiffs claim that by agreement they were to be supplied with twenty couplings a day for a year, and that in April last orders were not filled. The defendants claim nonexistence of any agreement, and if any contract had been made by their late president it was not sanctioned by the board of directors.

The Baldwins, British locomotive builders, are seriously considering the advisability of establishing a plant in the Maritime Provinces, in order to compete with the Americans. A factory in Canada would be of great value both as a source of employment and as a benefit to the Empire. It is only by increasing the manufactories here that Canada can help Britain in her unemployed problem, and the Canadians would do well to assist in the establishment of these large enterprises.

The Winnipeg General Power Company started to extend their lines into the city, but were stopped by the city engineer and the chief of police. The company claim that the right to enter Winnipeg is embodied in their charter and will apply to the Government for permission to do so. The city intends to run its own municipal power and has secured water sites for that purpose, and for this reason will shut out the Winnipeg Power Company, which is controlled by Mackenzie & Mann.

The Great Northern Railway is to construct a connecting line between their Similkameen county system and their trunk line. The object of this is to more easily get coal for the Hill railways and steamships. At present most of the coal used by the Hill people is brought from Montana, which, as well as being a long haul, does not give them the high quality of coal that is to be had from the Similkameen mines. The construction of this road will be commenced in about three months.

A number of Minneapolis capitalists have purchased the Shannon lumber interests in British Columbia, which comprise in all 30,000 acres of timber land and a mill site at Port Henry, for a sum exceeding $80,000. The purchasers among whom are W. W. Cargill, John Graham and Mr. Matthews, will erect a large mill on the site and will cut timber for the Canadian Northern on a contract already secured. They have also tendered for a large Grand Trunk Pacific contract, and will export ties and timber to Mexico and the Panama Canal.

Amongst special apparatus at present being completed by the Smart-Turner Machine Co., Limited, Hamilton, are an automatic spike machine for Geo. Barr, Chicago, smoke stacks, Crow's Nest Pass Coal Co.; tilting tumbling barrel, the Canadian Steel Goods Co.; wire crimping machine, the B. Greening Wire Co.; five-ton hand-power traveling crane, E. Leonard & Sons, London; wire fence loom, Frost Wire Fence Co., and a direct connected centrifugal pump and motor for the Hamilton Cataract Light, Heat & Power Co.

It is stated that more aluminum is manufactured in Niagara Falls than in any other place in the world. The aluminum works at that place have been in operation just ten years, and in that period the development of the aluminum industry has resulted in an enormous demand for the metal. In 1904, 8,600,000 pounds of aluminum were made in this country, an increase of 1,100,000 pounds over the preceding year. At the end of the first decade of manufacture in 1893 the total of the American product was only 339,629 pounds.

The Trail Smelter, Trail, B.C., received last year 227,000 tons of ore. From this ore was produced 82,000 ounces of gold, 1,360,000 ounces of silver, 13,280,000 pounds of lead, and 4,520,000 pounds of copper. An electrolytic lead refinery was put in, and the smelter has for some time past been receiving the crude lead ore from the Slocan mines. The result of this has been that they have been enabled to carry on the whole process of lead production, from the crude ore to the finished lead pipe, which is now put on the market direct from the works.

The fourth annual report of the president to the shareholders of the Chicago Pneumatic Tool Co. was issued on Feb. 8, which shows a large extension of business, and profits amounting to 9.15 per cent. available for dividends, of which 4 per cent. was appropriated to pay dividends and the balance, amounting to $315,134.39, carried to surplus account. During the past year the company acquired the business of the Philadelphia Pneumatic Tool Co., Philadelphia, and the Canadian Pneumatic Tool Co., Montreal, which company is now conducting the Canadian business.

Fetherstonhaugh & Co., patent solicitors, Canada Life Building, Montreal, publish the following list of patents recently obtained through their office. E. How, Hillsburg, Ont., draft equalizers, C. H. Bennett, Ottawa, water coolers; J. Murphy, Ottawa, means for combating anchor ice and frazil; G. Wettlaufer, Stratford, Ont., brick making machines; Byron W. Guthrie, Montreal, vent valves; Carl R. Salmen, Montreal, fire lighting apparatus; Joseph Ward, Montreal, display envelopes; Thomas E. Ainley, Uxbridge, Mass., fleece carrier; the Anti-Mal-de-Mer Belt Co., Montreal, abnominal belts.

Below will be found a list of Canadian patents recently secured through the agency of Messrs. Marion & Marion, patent attorneys, Montreal, Canada, and Washington, D.C. Information relating to any of these will be supplied free of charge by applying to the above-named firm. Stuart R. Fry, Killarney, Manitoba, railway rail; Hilary Querlarney, Man., railway rail; Hilary Quertier, Dunedin, New Zealand, apparatus for clearing the rails of tramways and the like; Simon Belanger, St. Jean Baptiste, Man., seed drill attachment; George Laporte, Campbell, Neb., U.S.A., acetylene generator; Archibald Turner, Leicester, Eng., speed indicators and recorders; Allan Gillender, Longueuil, Que., stove pipes; Edwin Sunderland, jr., St. John, N.B., disinfecting apparatus; Archibald McDonald, Montreal, automatic smoke preventing apparatus;

Ernest Renaud, Montreal, Que., semaphore operating means; John W. Tierney, London, Eng., pneumatic hammers and similar tools; Philippe Vidal, Ste. Cunegonde, Que., smoke consumer; Wesley Albt. Beelin, Portage la Prairie, Man. vehicle bearing; Elie Perron, Chicoutimi Basin, Quebec, sewing machine; Martineau & Prevost, Montreal, Que., water trap.

The Western Fuel Company are opening up the coal mines at Departure Bay, B.C., that were abandoned thirty years ago on account of having supposedly been worked out. Recent investigations, however, have revealed the fact that this district is rich in coal deposits. At present extensive operations are being carried on there again, and the latest improved facilities for coal mining are being employed.

Peterborough is expectant of great development upon the completion of the Trent Canal. Mr. D. Hughes-Charles, president of the Board of Trade, states that Mr. Robert Stuart, of the American Cereal Company, informed him that upon the completion of the canal his company would erect a 5,000-barrel flour mill. A mill of this daily capacity would be the largest in Canada, and would mean a great deal for Peterborough.

The Niagara-Welland Power Co., of which Harry Symons, of Toronto, is president, have filed their plans at the York County registry office, showing the route of their transmission wires through the County of York to the terminus in the City of Toronto. These transmission wires will parallel the Grand Trunk from the town line of Peel township into the Village of Weston; thence to Toronto Junction and along St. Clair avenue into the City of Toronto.

Canada's trade with Jamaica during 1905 has been very satisfactory. The Canada-Jamaica steamship line of carriers have materially assisted in the development of this business and are about to put on a line of vessels especially constructed for this trade. The Elder-Dempster Company also purpose putting on an up-to-date fleet of steamers to run from Halifax and St. John in the Winter, and Montreal in the Summer, to cater to this carrying trade. This innovation will be very welcome and will create still closer relations between the colonies.

As a result of the efforts of the recently inaugurated Board of Trade of Watford, a proposition has been received from the Lloyd Automatic Wire Weaving Co., of Toronto. The company asks for a loan of $15,000, a free site, and exemption from municipal taxes, the loan to be repaid in twenty annual installments, without interest. The company agrees to employ twenty-five hands at the end of the first year, thirty the second and thirty-five the third year. They will also erect a factory 50 x 150. The by-law will be submitted to the ratepayers in February.

The Tariff Commission held a session at Londonderry, N. S., recently, Messrs. Fielding and Paterson attending. Thos. J. Drummond, president of the Londonderry Iron Co., asked for an increased duty and continuance of the bounty on pig iron. He claimed that the duty and bounty combined amounted to only $2.72 in 1906, and after June, 1907, three would be no bounty. He asked that a bounty of $2.00 a ton be paid for a further period of five years so as to give protection equivalent to $2.50 per ton, regardless of British preference. The chief competition was from Great Britain. The Montreal Pipe Co. asked an additional duty on iron pipe to enable them to compete with Scottish pipe makers. B. F. Pearson, M.P.P., asked for a large bounty to furnaces using native ore.

W. K. Lowden, of St. Lambert, Que., has recently ordered one 14 x 24 inch Robb-Armstrong Corliss engine, and the Moffatt Stove Co., Toronto Junction, Ont., have ordered one 13 x 24 inch Robb-Armstrong Corliss engine. The Town of Westmount have ordered for their new electric lighting plant, two 13 and 25 x 14 inch Robb-Armstrong, cross compound, vertical engines, and one 8 and 14 x 8 inch Robb-Armstrong cross compound vertical engine. These engines are arranged for direct connection to electric generators and are of the English vertical high speed type.

Vancouver lumber mills report extremely busy times ahead. In fact, some of them are already so busy they are refusing offered trade. Most of the mills have run all Winter without a shutdown, and have been as busy as in the Summer. With the expected demand for railway construction timber, it is hardly possible for the mills to cope with the trade which will offer. Demand from the Northwest has not begun yet, and none of the mills are at present stocked up. Most of them assert that they have not a foot of the ordinary one-inch dressed and matched seasoned lumber, as flooring, siding and "V" joint, in stock. The addition of two large mills at New Westminster to the cutting force of the coast mills will not take care of the increase in trade.

Sir Thomas Shaughnessy, in making the announcement that Quebec would be the terminus for new ocean-going boats which the C.P.R. will put on, stated that Canada has scarcely a port suitable to accommodate these vessels. Montreal is being fitted up with the requisites of a large steamship terminus, but the St. Lawrence channel would have to have a depth of not less than 30 feet and a width of not less than 300 feet, with 500 feet at the bend in order to make it safely navigable for the two large ships that will be put on. This deepening and widening scheme has been considered by the Government, but it would take about seven years to complete the work, and in the meantime Quebec will be the terminus. Halifax was suggested, but the long rail haul made it impossible.

The Town of Port Arthur has entered into an agreement with Hedges & Burleigh, two Boston capitalists, the result of which will probably be the erection of a large steel tube works this year. As already mentioned in Hardware and Metal, the town will purchase one hundred acres of land for a site at Bare Point, and take $100,000 of the company's bonds at par. For their part, Hedges & Burleigh agree to erect a plant costing three-quarters of a million dollars, and commence with two hundred and fifty men. Work will be commenced within three months from the ratification of the agreement by the ratepayers.

J. S. Larke, Dominion Commercial Agent in Australia, reports that Australian conditions generally are improved, and that 30,000,000 bushels of wheat will be exported. The United States manufacturers are reducing prices to meet the preferential tariff in New Zealand. On nails the reduction is from 12 to 20 cents per hundred pounds, in order to prevent Canadian nails coming on the market. The Australian Parliament has risen without considering Canada's offer of reciprocity, or doing anything to reduce the handicap that was placed on Canadian trade by the order adding the cost of inland freights to the value of goods, for customs purposes.

Brantford may secure a new industry in the shape of a brick manufacturing company. Two Americans, J. L. Richardson and L. W. Smith are promoting the scheme, and are said to be backed by a well capitalized company. Their article is known as the "sand lime brick," and is made under the Schwartz American patent. It is a cheap brick, and at the same time a good one, and is being used largely on the other side. Options are held on three different properties, and if the company decides to locate there they will put in a plant valued at $37,000. About fifteen men will be employed.

The Canadian Pacific Railway Co. are considering the advisability of substituting electricity for steam as a motive power, and are making inquiries as to cost, with a view to making some experimental tests. If they decide to try the use of electric motors in the running of their trains, the line between Montreal and Quebec will be the first branch equipped, and the tests will be made during the next six months. Should electricity prove successful, the system of electrification will be gradually extended to other branches. Shawinigan Falls will furnish the energy for the first tests, and in the event of their adopting electricity, Niagara Falls will no doubt be drawn on for some of the Ontario lines.

A very strong case in favor of Government subventions to assist in establishing a steel shipbuildiug industry was presented to the Tariff Commission at Halifax by a strong deputation, which urged the importance of this enterprise not merely in the interests of the Maritime Provinces but from a national standpoint. The growing commerce of Canada demands the establishment of a Canadian merchant marine, and this prospectively great factor in our national development cannot be established without Government assistance, and that assistance must be adequate to insure the successful initiation and prosecution of the industry. The request is for a bounty of six dollars a ton, which with the natural facilities and materials at hand should be sufficient to induce capitalists to take up the project.

New Methods of Iron Production.

Mr. Sontum, commercial agent for Canada in Sweden and Norway, reports the discovery of two very important inventions in connection with the iron and steel industry, which are at present attracting considerable attention. The inventors are two Swedish engineers, Messrs. Grondill and Kjellin, who have found a new method for producing iron from the ore. By Mr. Grondil's system the ore is crushed to fine dust and the iron is drawn out by the aid of strong magnets. It is then moulded into the form of bricks. Mr. Kjellin uses electricity for the same purpose. The patentee has closed contracts with French, German and Italian firms for the employment of Mr. Kjellin's method in the production of from two to three million tons of iron and steel per year. Similar agreements for the production of iron and steel under the Grondil method have been made with other firms, notably the Krupp works at Essen, Germany.

* * *

More Power for Ottawa.

Now that the dispute between the different parties interested in the Chaudiere Falls has been settled there is every reason to expect that further utilization of this magnificent water power will be made, and that more power will be available for individual manufacturers at the capital.

* * *

Engineers' Club of Toronto.

At the February meetings of the Engineers' Club of Toronto the following papers were read and discussed: "The Microscopic Structure of Iron and Steel," illustrated by lantern slides, by Principal John Galbraith; "The Railway Franchise," by Robt. McKay, and "Suburban Railways," by C. H. Wright.

* * *

Attractive Souvenirs.

W. T. Glover & Co., Manchester, have sent two interesting souvenirs, one in the shape of a pipe cleaner and the other a daily calendar. The former is handsome in appearance and an addition to any bachelors den. The calendar contains a large sheet for each day, giving interesting and valuable technical information.

* * *

Sylvester Manufacturing Co. Expanding.

Heretofore the Sylvester Mfg. Co., at Lindsay, Ont., were known particularly as being large manufacturers of agricultural implements of all kinds, in which they catered not only to Canadian western trade, but to the European and South African as well. Recently, however, they have undertaken the manufacture on a somewhat extensive scale of gasoline engines of a range from 1 1-2 to 35 H.P., and in which they are meeting with no small success. This firm now employ from 150 to 200 hands and are running their entire equipment of modern machinery at its fullest capacity. Railway sidings with both the Grand Trunk and Canadian Pacific Railway give the company ample railroad facilities.

* * *

New Boiler Shop.

The G.T.R. shops at Stratford are to be further enlarged by the addition of a new boiler shop and new plate shop, at which time the plant will have accomodation for 1,500 men. The dimensions of the boiler shop will be 125 x 220 feet, and the plate shop about 125 x 50 feet. The present boiler shop will be used for a large erecting shop, affording capacity for 12 new engines.

* * *

Frost & Wood to Rebuild.

The main part of the Frost & Wood Company's plant at Smith's Falls was destroyed by fire on Friday, Feb. 9, and the big machine shop with its very costly machinery, the carpenter shop with its entire contents, the paint shop and the plow shop are a mass of ruins. Their large blacksmith shop was badly damaged, but not ruined. In a short time it can be repaired and in working order again.

The fire is supposed to have started in the vicinity of the dry kilns, and notwithstanding the fact that two nightwatchmen were on duty it got considerable headway before it was discovered. The fire was a hard one to fight on account of the size and arrangement of the buildings, and burned fiercely from 3 a. m. till 7 a.m., when it was gotten under control. The loss, while extremely heavy, was well covered by insurance. The large molding shop together with a pattern building, which adjoined it, were unharmed and this leaves the company in an excellent position to go right on and supply the demand for their machinery. Their big warehouse containing the entire season's output was untouched by the flames, and, while the company is hampered for the time being, they are very far from being "out of business" or incapable of supplying machines to fill their orders.

* * *

Foundry Foremen Association.

The second foundry association to be established in Canada has been organized in Montreal, when David Reid, of the Canadian Westinghouse Co., Hamilton, president of the Hamilton branch, went to Montreal for that purpose. The new officers of the association are: J. B. Rountree, the Locomotive Machine Co., president; Essery, Warden, King & Co., vice-president, and J. F. Gaffney, the Allis-Chalmers-Bullock Co., Limited, secretary and treasurer.

* * *

Stationary Engineers.

A communication has been received from the chairman of the central committee of the Stationary Engineers of Ontario enclosing literature on the subject of the proposed legislation in the interests of that body, for which they are at present petitioning. Space will not permit publication of this, but it is earnestly hoped that their efforts will meet with success and that more stringent legislation be brought into effect along the line of raising the status of the stationary engineer and making it compulsory for anyone in charge of a boiler of 50-h.-p. or over to pass an examination giving him the necessary qualifications.

* * *

Bertram Works Completed.

The present additions to the works of John Bertram & Sons Co., Dundas, have been completed as far as building operations are concerned, the new foundry building being ready for occupation. The equipment for this building is nearly all installed and the power house for distributing the electric power in nearing completion. In this power house will be installed transformers for receiving the power from the Cataract Power Co., the total capacity being 800 H.P., which makes allowance for an extra set, to insure continuity of running in case of accident to those in operation. In addition a complete compressor plant is under way and a 175 k.w. motor generator set for direct current used on foundry crane and variable speed machinery in the machine shops. In addition, room has been provided for a 1,000 gallon underwriter fire pump. The entire additions, with the exception of some installations, are completed and are modern in every respect.

* * *

Canada's First Cement Elevator.

The cement elevator and steel tower built by the Brackman-Ker Milling Co. at Strathcona, Alta., is practically completed. The tower is of steel 6½ feet square and 112 feet high. The elevator is 82 feet to rim and 88 feet to peak and has a capacity of 100,000 bushels. It is 40 feet in diameter outside measure and 39 feet inside, as the walls are six inches thick. About 560 barrels of cement, 1,120 barrels of sand and 1,680 barrels of gravel were used in the construction. Three-quarter-inch iron rods wind spirally around the centre of the wall for the first 40 feet, ½-inch iron rods in the same way for the next 30 feet and then 7-16-inch iron rods from 70 feet to the top. These spiral iron rods are secured to upright half-inch straight iron rods, 12 inches apart in the centre of the wall from base to summit. The latest improved rope-driven machinery is installed in a subterranean passage between the mill and elevator and is capable of discharging 2,000 bushels per hour into the mill. The design of the structure and accessories is that of Elsi Heidenrich, Chicago. The work was commenced September 15 and cost about $18,000.

Talk on Turbine Propulsion.

At the last meeting of the Engineering Society School of Practical Science, R. Warren, Science '04, gave an interesting lecture on the subject of the propulsion of steamships by means of the steam turbine, in which special reference was made to the design of propellers necessary for high speeds.

Companies Incorporated

The Canadian Key Registry Co., Winnipeg, have been incorporated with a capital of $1,000, to manufacture key rings, etc. The incorporators include F. J. C. Cox, R. A. Taunton and S. H. Matheson, Winnipeg, Man.

The Anderson Stone Quarry Co., of Amherstburg, has been reorganized with a capital stock of $1,000,000, and will begin operations in about two months. $50.000 has been spent in machinery and about 100 men will be employed.

The Croesus Mining Co. has been incorporated with a share capital of $500.000, for the purpose of carrying on a mining and development business. The provisional directors are Shirley Ogilvie, D. L. McGibbon and Travers Lewis; head office to be at Ottawa.

The Dominion Stove & Heater Works have been incorporated with a capital stock of half a million dollars, headquarters in Montreal. The provisional directors are L. E. Kimpton, H. L. Mitchell, R. I. Henicker, W. C. Strachan and W. G. Mitchell, all of Montreal.

The Western Canada Coal Mining Company has been incorporated with a capital stock of $50,000, for the purpose of carrying on a coal business. The provisional directors are J. W. Cockburn, J. A. Christie, W. A. Black, J. G. Dagg and S. H. Dagg, with head office at Winnipeg.

The Silver Leaf Mining Company has been incorporated with a capital stock of five million dollars, for the purpose of carrying on mining, milling and reduction operations. The provisional directors are C. A. Foster, J. H. Spencer and Mary A. Hodgson, with head offices at Toronto.

The Maybank Bronze Metal Co. has been incorporated with a share capital of eighty thousand dollars, with head office at Morrisburg. They will manufacture and deal in brass, bronze, babbit, gun and bell metal. The provisional directors are W. M. Maybank, H. H. Bradfield and C. A. Myers.

The Reinforced Concrete Company has been incorporated with a share capital of $200,000, for the purpose of carrying on a general quarrying and cement business, with head office at Montreal. The provisional directors are D. Loynachan, I. J. Donoghue, J. T. Bethune, A. W. Powell and J. L. Geoffette.

The Northern Ontario Copper Co. has been incorporated with a share capital of $500,000, for the purpose of carrying on a general mining and milling business. The provisional directors are J. A. Montague, O. B. Jury, Uriah McFadden, W. E. Gimby and A. C. Boyce. Head office to be at the Soo.

London Fence, Limited, Portage La Prairie, have been incorporated with a capital of $250,000, to manufacture wire, iron or wire fencing and gates, etc. The incorporators include J. S. Willmott, Portage La Prairie, Man.; H. G. Gray and A. E. Blashill, London, Ont., and A. E. Hinds, Winnipeg, Man.

The Ontario Sewer Pipe Co. has been incorporated with a share capital of $300,000, with head office at Toronto. They will manufacture sewer pipe, paving and building blocks. The provisional directors are J. J. Zimmerman, Andrew Dods, J. A. Macintosh, E. G. Morris and M. B. Peacock, all of Toronto.

Canadian Dredge & Construction Co. has been incorporated with a share capital of $150,000, for the purpose of building and operating dredges, derricks, tugs, lighters, etc. The head office will be at Midland, and the provisional directors are James Playfair, D. S. Pratt, Peter Potvin, D. L. White and W. J. Sheppard.

The Pratt & Whitney Company of Canada have been incorporated with a share capital of $100,000, for the purpose of manufacturing and dealing in machinery and tools. The head office will be in Dundas, and the provisional directors. R. C. McKinney, L. B. Morgan, C. L. Cornell, Henry Bertram and Alex. Bertram.

Messrs. A. Prudhomme & Fils, Montreal, have been incorporated with a capital of $145,000, to manufacture electric motors, dynamos, etc., and to acquire the business now carried on by A. Prudhomme & Fils, and Canadian Hardware Co. The charter members include A. Prudhomme, H. Godin and S. Beaudin, Montreal.

The Allward & McCormick Glass Company have been incorporated with a capital stock of $100,000 for the purpose of manufacturing and dealing in glass throughout Manitoba. The provisional directors are J. R. Allward, A. McCormick, G. F. Stephens, M. F. Christie, and L. C. Stephens, with headquarters in Winnipeg.

The Anthony Wire Fence Company of Canada, with head office at Windsor, has been incorporated with a share capital of $100,000 for the purpose of manufacturing and selling wire fences and machinery for making same. The provisional directors are D. P. Anthony, T. C. Harris, J. C. Hitchshu, J. W. Nixon and C. B. Anthony.

The Brantford Roofing Company have been incorporated with a share capital of $100,000 for the purpose of manufacturing and dealing in roofing paper and materials. The provisional directors of the company are Daniel Henry, C. L. Millhouse, W. D. Shultz, G. S. Matthews, G. C. Shultz, A. H. Elliott and Joseph Cobbledick. Head office to be at Brantford.

The Smith's Falls Foundry & Malleable Company have been incorporated with a share capital of $100,000, for the purpose of manufacturing stoves, ranges, furnaces, gasoline engines and malleable iron goods. The head office will be at Smith's Falls and the provisional directors are Adam Foster, W. A. Gray, John McEwan, Alexander Stephens, Matthew Ryan, A. G. Farrell and D. F. Wood.

The Capital Scale, Brass & Iron Foundry Company, with head office at Ottawa, has been incorporated with a share capital of $40,000 for the purpose of taking over the stock and good will of Gorman, Miller & Dittman, and continuing the manufacture of scales, brass work and weighing machines. The provisional directors are R. B. Gorman, F. Miller, A. E. Dittman, L. J. Kehoe and E. P. McGrath.

MACHINERY BUYERS' DIRECTORY.

Readers of CANADIAN MACHINERY are invited to use this directory as a ready reference when seeking to buy any machinery or machinists' supplies. In it will be found a list of goods made by leading Canadian firms and by the principal firms in other countries who are devoting especial attention to the Canadian market. It is the intention of the publishers of this paper to issue a desk index for machinery buyers, and all advertisers are invited to send in full list of lines manufactured.

Acids.
Canada Chemical Mfg. Co., Ltd., Toronto

Abrasive Materials.
Canada Machinery Agency, Montreal.
The Canadiau Fairbanks Co., Montreal.
H. W. Petrie, Toronto.
Rice Lewis & Son, Toronto.
Williams & Wilsou, Montreal.

$20

For twenty dollars you cau secure half page advertisement in the Annual Spring Number of Hardware and Metal.

This Number will be published in March and a copy will be mailed to every Hardware Merchant and Plumber, Stove and Tinware Dealer in Canada.

Last year's number contained advertisements from 150 of the best firms in Canada and United States.

Our number this year will contain about 200 pages and will be the best number ever sent out from the MacLean Publishing Co.

FREE CLASSIFICATION IN OUR

BUYERS' GUIDE

The Buyers' Guide will be issued immediately after the publication of our Spring Number and will contain a list of all the lines manufactured by our advertisers.

A copy of this Buyers' Guide will be sent to every man in the trade from Halifax to Vancouver.

CONDENSED MACHINERY ADVERTISEMENTS.

Rates—25c. for twenty words or less; 1c. a word for each additional word.

AGENTS WANTED.

WANTED — Practical machinists, to act as representatives of CANADIAN MACHINERY in the shops they work in; liberal commission offered. Address Business Manager, CANADIAN MACHINERY.

MACHINERY FOR SALE.

FOR SALE—One 3-phase, General Electric Co. of Sweden, generator; 100 k.w., 500 v., 60 cyc., 7,200 alt.; complete with exciter and switchboard, on which are mounted volt meter and amin meter. Apply Sandford Furniture & Woodenware, Limited, Fenelon Falls, Ont.

BUSINESS CHANCES.

FACTORY FOR LEASE—Suitable for large works; combination metal-working and wood-working; exceptionally good terms. Apply to Business Manager CANADIAN MACHINERY, Toronto.

MACHINE SHOP — Established 12 years; lathes, drills, grinders, etc.; patterns for 3, 6, 15 and 25 h p. gasoline engines; automobile engine patterns for 6, 12 and 16 h.p.; also several other patterns and engines in stock at present; repair trade paying big profits; in Canadian town of 45,000 inhabitants; must be sold at once on account of ill-health of proprietor; price about $3,000. Box 301, CANADIAN MACHINERY, Toronto.

FACTORY AND WAREHOUSE in Galt, Ont., 70 h.p. boiler; sprinkler system, heating and lighting throughout; immediate possession. Galt Knitting Co., Galt, Ont.

EDUCATIONAL.

MECHANICAL DRAFTING Pays—Complete course, $5. Evening Press, Collingwood, O.

MODERN MACHINIST—Just the book for machinists, etc.; 320 pages, 250 illustrations; price $2.50 Book Department, MacLean Pub. Co., Toronto.

Machinery For Sale

Owing to the expiration of our lease, we will vacate our present premises, cor. of St. Catherine and Peel Streets, on or about May 1st, 1906, when we will dispose of

1 50 h.p Horizontal High Speed Laurie Engine, with 10 inch wide driving belt.
1 45 k.w. Dynamo (made by Can. Gen. Electric), complete with marble switchboard (7 switches.)
1 Feed Water Heater.
1 Northey Pump, 3x2x7.
1 Northey Pump, 4½x2¾x4.
1 Hydro Steam Machine for passenger elevator, with 950 feet of rope (only in use two months.)
1 Ceiling Machine for freight elevator.
1 8 h.p. Upright Engine.
1 2½ h.p. Motor, 110 volts d.c.
32 Arc Lamps, 52 volts d.c.

About 60 feet of Shafting, Hangers, 8 Pulleys, and a quantity of 3-inch Belting.

A quantity of 1½ inch Steam Pipes and Valves, including asbestos covering for same.

1 small Hand Parcel Elevator, etc., etc.

The above machinery can be now seen in running order by applying to Mr. Walker on the premises at present occupied by

The Hamilton Co.
St. Catherine and Peel Streets
MONTREAL

MACHINERY WANTED.

POWER punch and shear; London Machine Tool Co. make preferred; second-hand will do if in good order. Address T. E. Bissell, Elora, Ont.

WOODWORKING machinery; second-hand planers, moulders and other woodworking machinery in good repair. J. H. Hicks & Sons, Bridgetown, N.S.

ENGINE and boiler, mounted on skids; new or second-hand; about 10 or 12 h.p.; must be in good shape; also gasoline engine, same size; give price and full particulars and how long it has been running and where, The Huntsville Foundry Co.

WANTED—17 to 22 ton standard gauge switching locomotive; also standard gauge revolving locomotive crane, with clam shell bucket for unloading coal; both must be in first-class condition; give full specifications and quote prices, The Lakefield Portland Cement Co., Limited. Lakefield, Ont.

IRON WORKS FOR SALE

Including Foundry, Machine and Boiler Shops, as a going concern. Located in Western Canada, doing good business and up-to-date plant. Apply to

Pilkington's Power Hammers

Driven by Electric Motor or from Line Shaft
Used by all the Principal Engineering and Shipbuilding Works, Railway Companies, Mines, etc.
ALSO NEW COMPRESSED AIR HAMMERS
Worked from Separate Compressor.
We can save you over 50 per cent. in power consumption as compared with other types.
These Hammers have Compound Cylinders and require a surprisingly small quantity of air.
HAVE YOU STEAM HAMMERS?
We can convert them to our new type AIR HAMMERS.

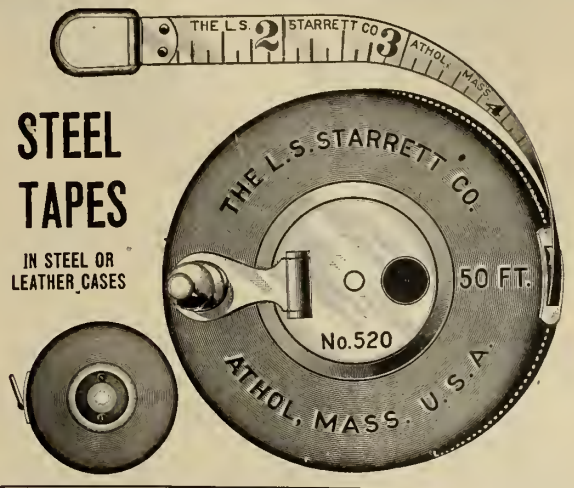
BUTTERFIELD & CO., - - ROCK ISLAND, P.Q.

STARRETT TOOLS

ARE THE STANDARD

FOR ACCURACY, WORKMANSHIP, DESIGN AND FINISH



STEEL TAPES

IN STEEL OR LEATHER CASES

In our tapes the figures denoting feet are smaller than those denoting inches. Two reasons for this :

This dissimilarity of figures materially lessens (in fact ought to entirely prohibit) the liability to erroneous readings that frequently occur through the uniformity of all figures in steel tapes of other makers.

The smaller figures, denoting feet, allow the graduation line under each to be plainly visible, instead of being obliterated by the usual larger figure.

Graduated in feet, inches and eighths of an inch, or in feet, tenths and hundredths of a foot.

SEND FOR FREE CATALOGUE, No. 173, OF FINE MECHANICAL TOOLS.

What Do You Read?

Reading matter is a great gift to mankind. It is the choice inheritance of the age. Observation, reading, thinking; these three should go hand-in-hand, and when they do, then the man who reads widely has a weapon placed within his hands before which the man who does not read may well tremble.

THE BUSY MAN'S MAGAZINE contains the cream of the world's current literature condensed for busy people, besides giving its readers clever character sketches of the men who are developing the resources of the Dominion.

THE BUSY MAN'S MAGAZINE
Is a Success

Unsolicited comment from one reader—we have many similar letters—they arrive daily:

THE INGERSOLL PACKING CO.

Ingersoll, Dec. 14th, 1905.

We would not like to miss the future copies of THE BUSY MAN'S MAGAZINE, if the contents continue to be on a par with the November number, which to our mind is a particularly fine number, and which we enjoyed very much.

TECHNICAL BOOKS

THE MODERN MACHINIST.

BY JOHN T. USHER.

8vo. 320 Pages. 250 Illustrations.

PRICE, $2.50.

SPECIALLY ADAPTED FOR MACHINISTS, APPRENTICES, DESIGNERS, ENGINEERS AND CONSTRUCTORS.

A Practical treatise embracing the most approved methods of modern machine shop practice, and the applications of recent improved appliances, tools and devices for facilitating, duplicating and expediting the construction of machines and their parts.

A new book from cover to cover, which every machinist and practical man should possess. Every illustration in this book represents a new device in machine shop practice.

Special Chapters on Measuring Instruments, Vise Work, Chasing, the Erection of Machinery, Planing, Shaping, Slotting, Milling, Lathe Work, Drilling, and many other kindred topics considered point by point. This work is thoroughly up-to-date and was written by one of the best known and progressive machinists of the day.

Fowler's Boiler Room Chart.

An Educational Chart showing in isometric perspective the mechanisms belonging in a modern boiler room. The equipment consists of water tube boilers, ordinary grates and mechanical stokers, feed water heaters and pumps. The various parts of the appliances are shown broken or removed so that the internal construction is fully illustrated. Each part is given a reference number and these with the corresponding name is given in a glossary printed at the sides. The Chart, therefore, serves as a dictionary of the boiler room, the names of more than two hundred parts being given on the list.

It is educational in that, with it, the student will be able to learn of the construction and arrangement of the best type of boiler plant, and examine into the relations of the various parts, while the glossary gives the name of each piece and part that is shown.

This latter is so arranged that the names of any part can be readily found, or the name being given—the part and its functions are readily determined.

Size 14x28 Inches. Printed in Colors.

A CATECHISM ON THE

Combustion of Coal

AND THE PREVENTION OF SMOKE.

A PRACTICAL TREATISE FOR

Engineers, Firemen and all others interested in Fuel Economy and the Suppression of Smoke from Stationary Steam Boiler Furnaces and from Locomotives.

By WILLIAM M. BARR, M. E.

AUTHOR OF "BOILERS AND FURNACES," ETC., ETC.

One Volume—350 pages—85 Engravings.

PRICE, $1.50

This book has been prepared with special reference to the generation of heat by the combustion of the common fuels found in the United States, and deals particularly with the conditions necessary to the economic and smokeless combustion of bituminous coals in **stationary and locomotive steam boilers.**

The method of treatment consists of a systematic and progressive series of questions covering every detail relating to the combustion of fuels for the purpose of generating heat; the answers to these questions are practical and direct, and to better illustrate certain subjects which could not otherwise be made clear, eighty-five engravings have been specially prepared which admirably supplement the answers to which they belong.

CONTENTS

CHAP. I—Fuels.
II—Some Elementary Data.
III—Atmosphere.
IV—Combustion.
V—Products of Combustion.
VI—Heat Developed by Combustion.
VII—Fuel Analysis.
VIII—Heating Power of Fuels.
IX—Steam Generation.
X—Stationary Furnace Details.
XI—Locomotive Furnace Details.
XII—Chimneys and Mechanical Draft.
XIII—Spontaneous Combustion.

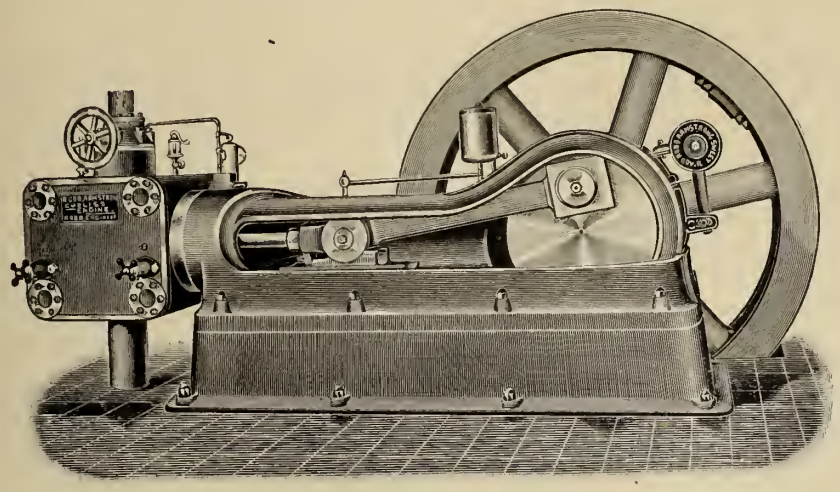
AN IDEAL STEAM PLANT

When you instal a power plant see to it that you get the best, the most efficient possible. Not only will it pay you, but it will give you unending satisfaction.

Note the following comment on a 350-horse-power Robb-Armstrong Corliss Engine and two 175-horse-power Robb-Mumford Boilers installed by us:



Medium Speed Heavy Duty Robb-Armstrong Engine.

"I will say without qualification that it is as fine a boiler and engine plant as I have ever had the pleasure of seeing for its size. The engine was working without heating and absolutely without any noise. I wish to congratulate you on your success in building this class of engine, and hope that we may have pleasure in dealing with you again."

Simplicity, Efficiency and Strength are Combined to the greatest degree in the Robb-Armstrong Corliss Engine

Sylvester Gasoline Engines

Are the best that skilled labor can produce.

They are easy starting; they are simple and reliable; they will give full power in the coldest weather. Made in sizes from 4 to 32 horse power in portable snd stationary and from 1½ to 12 horse power in marine. They will run on gasoline, coal oil or distillates.

The SYLVESTER Engine inspires confidence because it is so simple in construction. It is the cheapest engine to buy because there is nothing to get out of order.

The SYLVESTER Engine is handsome in appearance, substantial in construction, marvelous in simplicity, unequalled for effectiveness and durability.

THE HIGHEST AND MOST PERFECT TYPE OF GASOLINE ENGINE BUILT.

If you require to purchase, write for Catalogue and our 1906 Calendar. We will then send our Travelling Salesman to you

THE SYLVESTER MFG. CO., Limited, - - LINDSAY, ONT.

Canada's New Lubricating Graphite

SAVES OIL SAVES MONEY
SAVES TIME SAVES WORRY

A perfect lubricating graphite is demanded by practical engineers and those responsible for keeping machinery in motion. **Time is saved. Power is saved. There is no worry where Canada's New Lubricating Graphite is used. There is no equal.**

You must use only the the best "air-floated" Graphite. Ours is an impalpable POWDER, free from grit or any sort of impurity.

No journal will be damaged from over-heating or kindred cause if you use Canada Graphite, for unlike oil it associates itself with one or other of the rubbing surfaces, it enters every crack and pit and fills them. If the surfaces are ill-shaped or irregularly worn, the Graphite fills in and overlays until a new surface of a regular outline is produced.

Watch for our Ads. and we will interest you. they will convince you that we can save you money. Write for our Catalogues, Booklets and Samples,

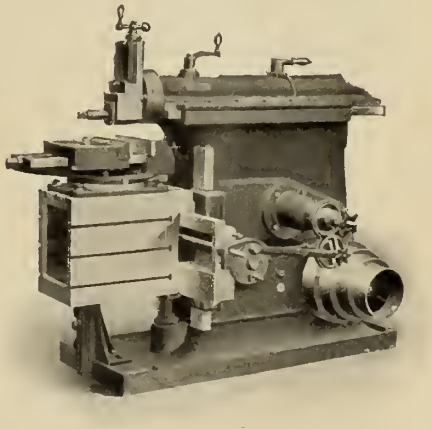
THE SHAPER

AN EVOLUTION IN SHAPER BUILDING

ORIGINALLY a machine set aside in machine shops ***FOR "ODD JOBS," NOW*** a powerful and rapid ***"MANUFACTURING MACHINE,"*** equal in importance to any in your shop. In other words, a ***MONEY-MAKING TOOL*** deserving the greatest consideration. You are, no doubt, familiar with the wonderful advance we have made in our "AMERICAN" LATHE construction, practically ***DOUBLING*** their ***EARNING CAPACITY.*** We have done the same thing with our Shapers, Planers, Radial Drills and Upright Drills. However, the subject of this discourse being ***"SHAPERS,"*** we wish to herewith introduce our ***"NEW AMERICAN SHAPER"***—a wonderfully powerful and accurate tool, especially adapted to the use of the new high speed tool steels. A few of its valuable features are as follows:

Massive, strongly ribbed column.
Extra high gear ratio for heavy duty.
Taper gib adjustments to sliding bearings.
Running bearings bushed to allow for wear.
Telescopic elevating screw (no hole in floor.)
Powerful feed with very wide range.
Heavy, powerful vice with steel-faced jaws.
Ram positioned and stroke set while running.



Sizes—16", 18", 21", 24", 28".

THE NEW "AMERICAN" SHAPER TAKES HEAVIER CUTS THAN MOST PLANERS. THINK OF IT!

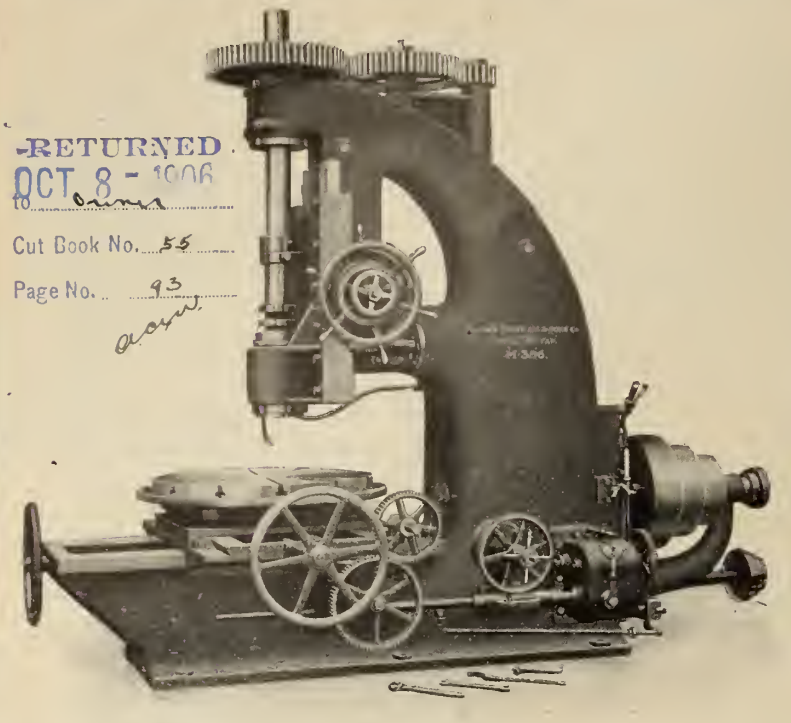
The Bertram Vertical Milling Machine



RETURNED
OCT. 8 - 1906
to Canada
Cut Book No. 55
Page No. 93
Canada

Has a spindle 5 inches diameter

and a combination of strong points which makes it the most powerful machine of its kind built. Attention is called to the powerful train of gear, making it possible to obtain a cutting force of 21,000 lbs. at the circumference of a milling cutter 5 inches in diameter. It has quick-change gear, all of steel. The driving cone has three steps for a 6-inch belt and has 12 changes of speed. All feed motions are conveniently located so that the operator need not leave the working side of the machine. The spindle has a vertical movement. The circular table is provided with power rotary, cross and longitudinal feeds, which are reversible as well as hand adjustment. For fuller information regarding this or any other of the Bertram lines of machine tools, write to

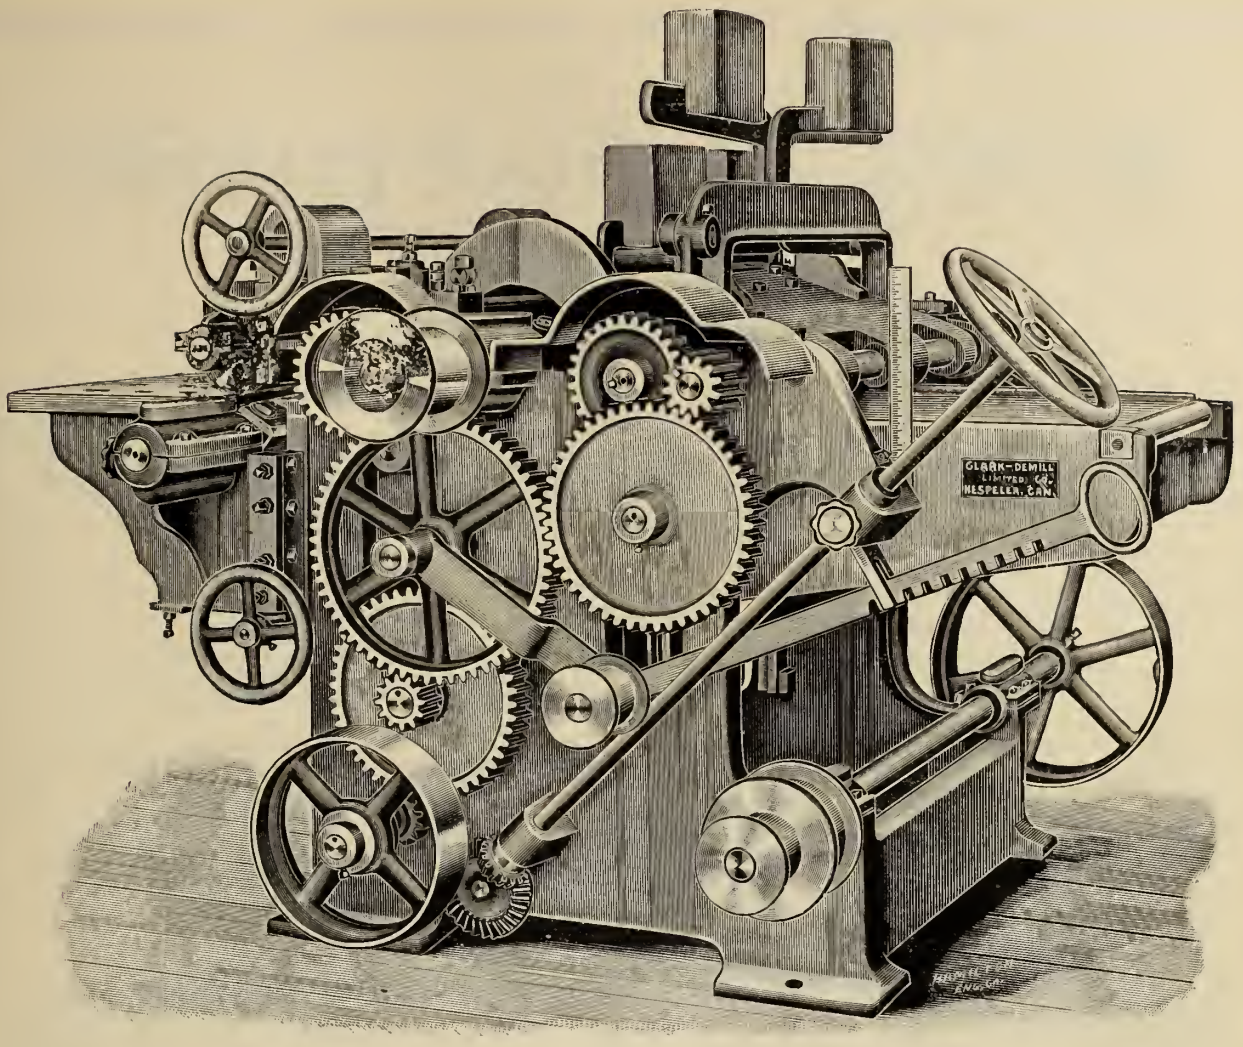
No. 1-14 Cutter and Reamer Grinder.

WE HAVE A FEW OF THESE MACHINES READY FOR IMMEDIATE DELIVERY

This machine is distinctly a cutter grinder, and was designed to fill the want for a machine to sharpen milling cutters of all kinds and shapes, without special fixtures or special-shape emery wheels, being heavy enough to eliminate all vibration and still be easily operated. It weighs about 1370 lbs. The table, which has a long bearing on the saddle, has a longitudinal feed of 20 in., cross adjustment of 7 in., with a vertical adjustment of 6 in. Cutters 1 in. to 14 in. can be taken between centres. The table can be used at different angles with the spindle in horizontal plane, by swiveling the knee around the column. The machine is compact, durable, adaptable and a necessity for the busy shop.

Becker-Brainard Milling Machine Co.

HYDE PARK, MASS.



Our No. 118 Double Surface Planer, 26 in. x 10 in. thick. Plain or divided Roll. Why spend time handling your material twice when you can have it surfaced two sides with one handling? Do you know what it is costing you to handle your material so often? Sit down and figure it up and you will find that it will pay you to buy a machine that surfaces your stock on both sides with one operation.

If this machine is not heavy enough for you, why, we make heavier, and will be pleased to tell you about them.

All work guaranteed to be of the highest order.

Modern Canadian Manufacturing Plants.

ARTICLE XIV.—The Standard Bolt & Screw Co., Limited, Toronto.

IN October of last year the Standard Bolt & Screw Co. was incorporated for the purpose of manufacturing what is known to the trade as milled goods, such as cap screws, set screws, machine bolts and nuts. The business was started by Mr. F. S. Jackson, for many years connected with the Diamond Machine & Screw Co., and since commencing operations Mr. Jackson has taken control of the shop and acted as superintendent. The officers of the company are: President, A. A. Dickson; vice-president, Dr. John Ferguson; secretary, P. S. McKergow.

Building and Plant.

Manufacture is carried on on the lower floor of the large new factory at the corner of Sorauren avenue and Dundas street, which is of solid brick on concrete foundations, the building being of slow burning mill construction. The plant is admirably suited for this work, being bright and cheerful and particularly well lighted. The main floor is 60 by 150 feet with separate office. At present there are about 18 machines in operation, most of which are Cleveland & Hartford automatic, but it is intended within the near future to add about 14 more of these machines, the space available being shown in the foreground of the view giving the power plant.

A new building is proposed and at present under way to be of concrete and fire-proof throughout, situated on the railway siding near the present factory, for the purpose of manufacturing hot and cold nuts and screws. This building, of which the end view is shown, will be capable of accommodating 60 automatic machines, together with hot and cold nut and bolt plants, consisting of presses and furnaces. This building is to be equipped with the latest labor-saving devices known, one of which will be an industrial railway running between the rows of machines for bringing in raw material and transporting the boxes of finished goods.

Raw Material.

When manufacture was first commenced considerable difficulty was experienced with the raw material from which the different lines manufactured here were to be made. Different lots were tested and experimented with and finally abandoned, until finally a suitable product was obtained for the highest class of manufacture. The stock used is round and square, from one-quarter to inch and a half, and hexagon from three-eighths to inch and a half, both iron and steel, the iron being used

Exterior View of New Plant—Standard Bolt & Screw Co., Limited, Toronto.

for case hardened set screws and the steel for cap screws, nuts, etc.

The power plant is situated in the southern end of the building, being under the control of the Southern Light & Power Co., whose plant at Erindale is now in course of construction. When the new building has been erected the firm will have its own power plant on the premises.

Manufacturing.

As will be seen from the two views illustrating installation, the machinery is conveniently arranged to afford

found a description of making cap screws by the latest method known.

It might be mentioned in passing that a screw plant running automatic machines necessarily requires a large amount of capital to instal it. The actual making of these goods is of considerable interest, one reason for this being that the machines run and turn out the finished product without the attention of a skilled mechanic.

Making Hexagon Cap Screws.

With one man to supervise the plant the remainder of the attendants may be

vances forward slowly but surely and mills this hexagon bar down to about $\frac{1}{2}$ inch in diameter and within $\frac{7}{8}$ of an inch of the cutting off place. This is called the roughing cut. The turret recedes and makes another partial revolution when a second hollow mill or cutter advances a little more rapidly this time. This is called the finishing cut and makes the screw exactly $\frac{1}{2}$ in. in diameter. The turret recedes again and makes another partial revolution, this time advancing with a circular tap which cuts the thread on the screw whatever length may be desired. When

Standard Bolt & Screw Co., Limited—Interior view looking north

greatest convenience to the attendants and for lighting. The machines are all run by motors, situated at convenient points running the two lines of shafting to which the different rows of machines are belted. The class of machines installed has already been mentioned and these are capable of turning out all classes and varieties of screw work, including bolts and screws of every description, loose ledger binding posts and gas engine valves. Each machine has a capacity of 150 to 800 screws a day according to size. It would be interesting to follow the course of manufacture in this plant and following will be

limited to a few men of but small experience. In watching the operation it was noticed that a workman placed a hexagon bar of steel about 12 feet long in one of the automatic machines, this bar being $\frac{7}{8}$ of an inch in diameter. The machine was then started and the first movement was for the bar to be carried forward about four inches. A revolving head or turret makes a forward movement in the opposite direction. This forces the bar of steel back a little and allows only $2\frac{7}{8}$ in. of the bar to be left to be operated upon. Another motion of the revolving head then takes place and a hollow mill or cutter ad-

the thread has been cut on the screw the machine takes on a backward motion and recedes, allowing the screw to remain intact with the full thread upon it. A side motion then occurs and a tool advances and cuts off this screw, leaving the bar ready to go forward again for another one. During the time this is going on a small rotary pump is constantly pumping oil on the screw while it is being made. This oil is used over and over. Practically no loss occurs but from evaporation.

The screw just made is then placed in a vat of hot alkaline liquid which cuts off any little oil or grease which may

adhere to it. The sides are then ground off smooth and placed in the shaving machine which finishes up a 2 in. x § in. hexagon head cap screw ready to be packed and shipped to the customer.

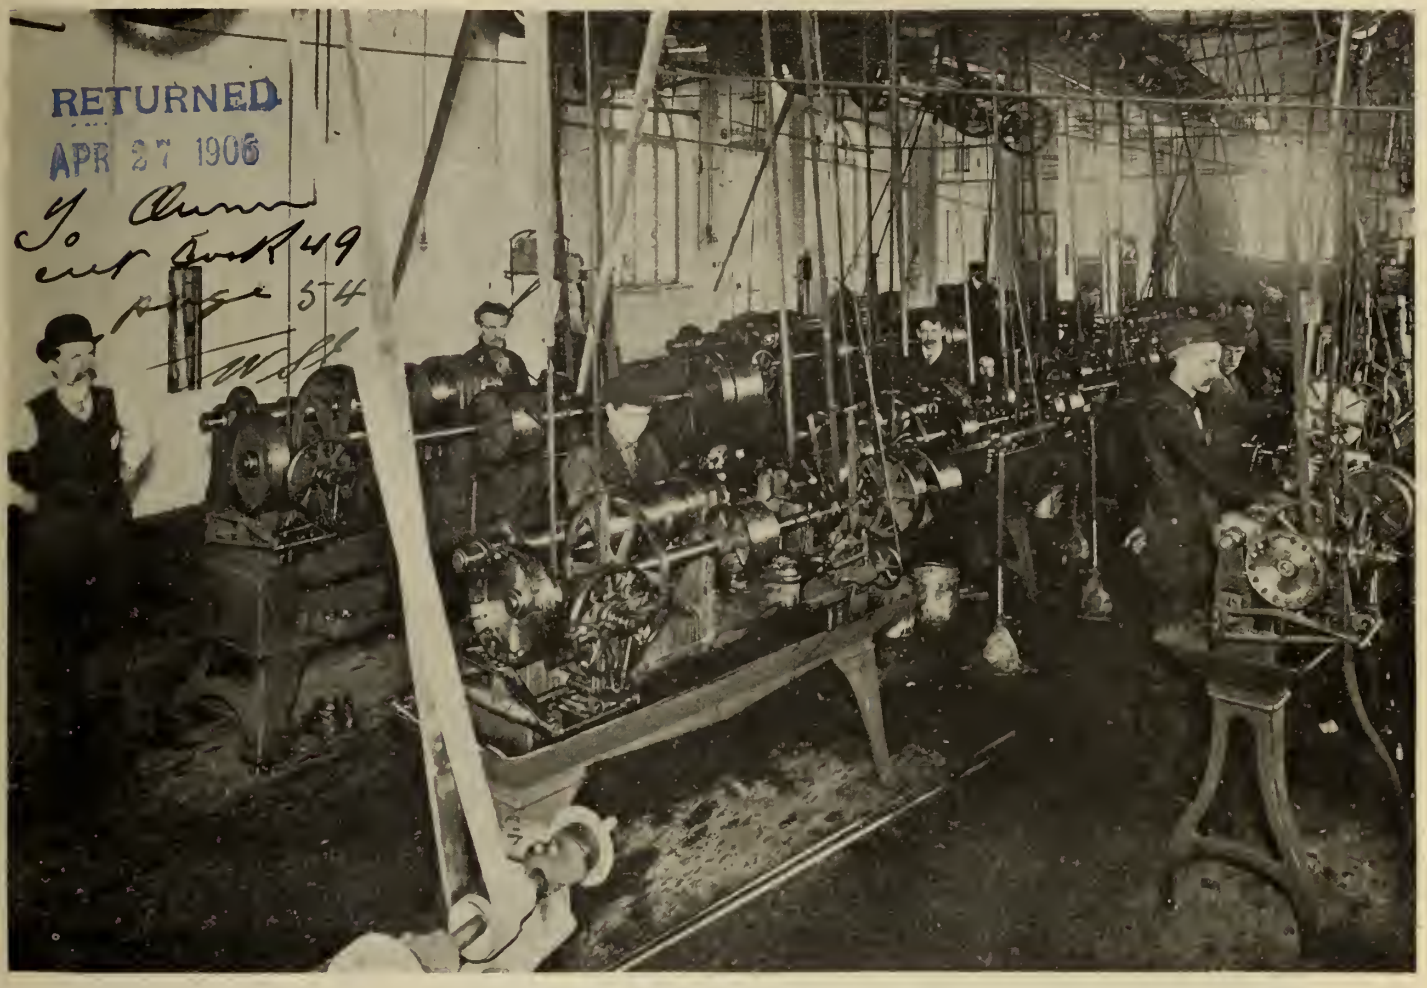
A machine of this type is capable of turning out hundreds of these screws in a day, and can be readily changed to produce screws of different sizes and lengths according to the requirements of the trade.

Set screws are made in a somewhat similar way, only the bar out of which they are manufactured is square. In some cases the point of the set screw is hollow or cup pointed, as it is called, and in others sharp pointed.

After the screws have been made and the heads finished they are then packed in boxes with charcoal, bones, etc., and placed in a furnace heated to a high degree of heat, and when they have been subjected to this heat the necessary length of time they are then plunged into cold water. This heating and cooling of them is called case hardening, which leaves the screw comparatively soft and tough on the inside while the outer portion is so hard that it cannot be filed or cut in any way. These screws are then packed in regular sized boxes ready for shipment.

All varieties of screws are made which are known to the trade as milled goods and the whole operation is very interesting and instructive, especially as one workman was attending to six of these automatic machines, placing in fresh bars as they were required and seeing that the machines were performing the duties which they were intended to do.

These machines never get sick; and are always ready to start their work when the power is applied to them. They never go on strike, all they ask in the form of wages is "Feed me with iron or steel bars and give me power and oil and I will do the rest."



Standard Bolt & Screw Co., Limited Interior view, looking south

---

DON'TS FOR MACHINISTS.

Don't blow into a hole that has dirt at the end of it.

Don't be afraid to tell your new ideas to your foreman.

Don't finger a piece of work while filing it in a lathe.

Don't use the side of your hammer to drive anything with.

Don't think all machinists are worth the same rate of pay.

Don't take advantage of your foreman's absence to "cut up."

Don't use a hollow-backed chisel for cutting oil channels.

Don't use a fine pair of dividers on rough and sandy scale.

Don't forget that O. K. means "Oll Korreekt," or all correct.

Don't try to grind a plug valve to a seat with coarse emery.

Don't try to make a flat surface with the tip of a file.

Don't think that a farmer boy cannot learn to be a machinist.

Don't file a piece of work when it chatters beneath your file.

Don't use a hard hammer to drive a mandrel into a piece of work.

Don't stop your machine while in the midst of a finishing cut.

Don't cut a rawhide gear on slow speed, as a fast speed is much better.

Don't gage the amount of work you do by the amount of pay you receive.

Don't mark fine tools with steel letters—squares and scales especially.

Don't forget that large pieces of cast iron may be bent by peening them.

Don't throw away all the short butt ends, when you are cutting up stock.

Don't bore out the lathe chuck when you are boring a piece of work in it.

Don't put a lot of "gingerbread" polish on work that does not require it.

Don't set a tool to take a finishing cut, without using an oilstone on it.

Don't try to rough out and finish large screw threads with the same tool.

Don't fit a bracket on a machine and leave its bolting surface crowning.

Don't think that what you know about a machine nobody else can find out.

Don't forget that your fingers are softer than gears, or iron of any kind.

Don't forget that the closer you can get your toolrest to the work, the better it is.

Don't make a piece of work to a blueprint and have it look like something else.

Don't forget that the warmth of your hand will increase the diameter of a shaft.

Don't mark machine part numbers bottom side up, when you are erecting a machine.

Don't build a machine with castings that have molding sand still sticking to them.

Don't drive a key into place unless you have some means of getting it out again.

Don't grind a tool to cut machinery steel the same shape as you would to cut tool steel.

Don't bore a large steam engine cylinder when lying in a horizontal position if you can possibly do it in a vertical position.

Don't carry dirty tools back to the store room, for the storekeeper to clean off.

Don't use a long-neck planer tool, when you can get at your work with a short one.

Don't serve an apprenticeship without learning to dress and temper your own tools.

Don't forget that a universal lathe chuck should be tightened at all of its screws.

Don't start up the engine without letting off the condensed steam in the cylinders.

Don't believe that lard oil is the only solution that is good to use on dies or tools in cutting threads, or wrought iron parts.

Don't boast that you can grind a cutting tool of any kind better than anybody else.

Don't say "I don't think that is right because I never saw it done that way before."

Don't put greasy fingers on cast iron either before or while taking a finishing cut.

Don't leave a shop, without leaving a clear record, so you may come back to it again.

Don't forget that the machine you are running and the space you are occupying, have to be paid for just as well as your time.

Don't file a shaft over a keyseat, in a lathe, if it is necessary to reduce the size; either take a cut with the lathe tool, or draw file it.

Don't forget, in tapping babbitt metal, lead, or any such soft stuff, to take the tap out and clean it after each full turn in.

Don't believe that a piece of work can be laid out, and drilled, planed, or milled as accurately as if it were done in the proper jig.—Machinery.

To Owner
car Book 48
page 31
W.L.

CANADA has got far beyond the day of doubt and hesitation as to its industrial future. A decade or so ago, when our confidence was less strong, a serious fire was a menace to the life of the average Canadian industry. No so to-day !

The accompanying views give an idea of the damage done by fire to two shops—the car shops of the Intercolonial Railway, at Moncton, N.B., and the implement works of Frost & Wood, Limited, Smith's Falls, Ont.

Needless to say, these works are being restored at once. In fact Frost & Wood have issued a folder entitled "Every Knock is a Boost," with illustrations of the ruins and with the promise to their friends and customers that the works will be replaced by a better, more up-to-date plant at once.

The view of the ruin of the Intercolonial shops at Moncton, N.B., shows the havoc wrought by the recent conflagration. The burned buildings covered a big area, and the loss to the Government in the destruction of the shops is placed at over $1,000,000. The heat had the effect of twisting and distorting the iron girders and trusses to the extent revealed in the illustration.

Remains of Frost & Wood Machine Shop, Recently Destroyed at Smith's Falls, Ont.

Ruin of the Intercolonial Shops at Moncton, N.B., where a Loss of $1,000,000 Occurred.

THE NIAGARA POWER PROBLEM TO ONTARIO.

WESTERN ONTARIO'S future possible and natural pre-eminence as an industrial centre is confronted by a spectre which is fast taking on form and substance and which jeopardizes the utilization of a natural heritage. The crisis has been reached wherein prompt action is essential and drastic measures seem inevitable.

It is stated on the authority of an hydraulic engineer delegated to look into the matter that of the power now under development on the Canadian side a large part has been contracted for by United States companies. The Ontario Power Co. has authority to develop 180,000 electric horse-power, all of which with the exception of 10,000 h.p. is said to be contracted for by the New York Central and the Westinghouse Co. to be used on the New York side, the price being $12.50 per h.p. The Canadian Niagara Power Co. may use sufficient water to produce 120,000 electric h.p., all of which has already been contracted for on the United States side. The remaining company, the Electrical Development Co., is the only one controlled by Canadian capital and the only one whose power is available for Canadian industries.

The people of Ontario and throughout Canada have been all too slow to realize this situation and unless some immediate steps are taken this enormous water power, every bit of which should be utilized to build up an industrial centre in Ontario equaled by none, will be lost to this country forever. A striking example of how Canadian natural resources are used to build up American industries is shown in the case of natural gas near Welland. Twenty years ago the Ontario towns in that neighborhood had counted on using this for industrial purposes, when a group of Buffalo capitalists secured the property and exported the total output of the gas field to Buffalo, thus aiding the manufacturers on the other side of the line at the expense of our own.

It now transpires that the report of the American committee of the International Waterways Committee suggests limiting the maximum amount of water to be diverted on the American side to 23,500 cubic feet per second and on the Canadian side 36,000. This may suit that branch of the committee but should never be considered, since there is on the Canadian side ten times the power available to develop as is possible on the American side.

Another point to be brought out and upon which the Ontario Power Commission and the commission representing the municipalities have done excellent work, is the definite supplying of power to the various municipalities and its cost delivered to the different places. Toronto now pays from $35 to $125 per horse-power a year for electric power. Although the report of the commission has not been made public it is known definitely that this committee has estimated that power can be delivered in Toronto allowing for depreciation, interest, etc., for less than $15 per horse-power a year. In view of this it might well be said that no more important question than that which faces the industrial interest of Ontario has yet arisen.

Just as we are going to press word comes from Ottawa that the Federal Government will assume control over the export of electric power, and that it has laid down a policy to govern its course. Right to export would only be granted subject to revocation at short notice and the companies developing the power would be subject to such rules and regulations as the Government saw fit to impose. The Canadian industries must have first consideration, and as far as our manufacturers are concerned it matters not whether the question is under federal control or under provincial regulation as long as the proper course is taken and the wholesale export of Niagara's power for indefinite periods prevented. The regulation of rates is another matter and the work now being done by the Ontario Government in that direction is bound to bear fruit towards that end.

BOON BY ELECTRIC SMELTING.

WHEN the Government first undertook to solve the problem of electric smelting even those most deeply interested and in the best position to judge were none too sanguine of its ultimate triumph. After Dr. Haanel prepared his exhaustive report on the subject of electric smelting the Dominion Government thought that enough had been shown to at least permit of setting aside a sum of money to carry on further investigations in Canada. Even then no definite statement was made by those connected with the investigations as to its practicability, and

the leading engineering papers were sceptical as to its final success. The announcement made by Dr. Haanel at the Canadian Club of Toronto on March 12 has entirely changed the trend of opinion in this direction, as he then announced to the world the complete triumph of electric smelting of Canadian ores, thus giving out a statement the effect of which will probably have more direct bearing on the future development of Canada than any heretofore made at any time.

He intimated that as a result of the investigations carried on Canada was at the edge of a greater commercial era than had been. It meant the commercial independence of this country inasmuch as we would in future be able to smelt our own ores. It meant that the vast ore deposits in Canada, of little value as far as any methods heretofore used could demonstrate, were now a priceless boon. It meant that these could be reduced on a commercial basis and produce a high grade of iron ore; in fact it was impossible to produce anything but a high-grade ore by the electric process. It was demonstrated that charcoal was as suitable for the production of iron by this method as coke, thus making the process entirely independent of coal. It meant, moreover, that the link between our water powers and our marvellous deposits of magnetite and sulphurous ores and their production into a highly marketable product had been forged, thus enhancing the value of our limitless water powers, which were, unlike mines, not subject to strike and final exhaustion.

The above represents the culmination of the metallurgist's dream for many years past, and means that Canada will now become a factor amongst the iron producing countries of the world. In these experiments several points were proven that have never before been cleared up in the different European laboratories and electric smelting furnaces.

The Government has done its share in this work, having demonstrated the possibilities, and it now remains for the people of Canada to develop this wonderful heritage, and there is no doubt that foreign capital will be anxious to lend a helping hand.

TECHNICAL KNOWLEDGE FOR CLAY WORKERS.

REGARDING the art and the technical details of manufacture of clay products, the practical workers in this line in Canada are somewhat at sea. This was brought out in a definite manner at an interview recently accorded by Hon. Frank Oliver and Hon. Dr. Pyne, at the Parliament Buildings, Toronto, to a delegation representing the Ontario Clay Products Manufacturers Association, at which they made a strong appeal for Government aid towards technical education in the ceramic art.

This idea deserves every encouragement. The association is not a combine nor a trade union, but a technical organization with the worthy object of mutual assistance in methods of manufacture and knowledge of the products used.

A representative from the School of Mines, Kingston, accompanied the clay workers and announced that there was a building available at Queen's University appropriate for the establishment of a course in ceramics in connection with the School of Mines. The request was such a modest one, namely, three thousand dollars a year for the establishment and maintenance of this additional technical education for the benefit of a growing and already important branch of manufacture, that there is no thought of an unfavorable reply from the Ontario Government.

To reach the highest development in any art, science or process of manufacture, the world's onward progress has already proven that technical education is essential. The men composing the Ontario Clay Products Manufacturers' Association have spent thousands of dollars experimenting that might easily have been saved had such information as would be provided by the course mentioned been available. The Province of Ontario cannot afford to miss this opportunity of adding another branch to our technical education and at the same time help to build up an industry that is already important but which is bound to have a much wider application as the industry is developed.

MUNICIPALITIES AIDING INDUSTRIES.

FROM time to time the importance to municipalities of their taking up the matter in a business manner of attracting industries within their limits, has been dwelt upon in these columns. Some of the Canadian towns and cities that have grasped the situation and acted accordingly have gone ahead by leaps and bounds as a result. Mention has already been made of places aggressive along this line for some years past, and we find amongst the list the towns growing most rapidly and having the greatest air of prosperity of any in the country.

Port Arthur, Ontario, is the latest town to take this up on an extensive scale. A by-law recently passed by the ratepayers allowed for the appropriation as a factory centre of fourteen hundred acres of land suitably situated for that purpose. In doing this the people have shown considerable foresight and business ability and have set a good example, and one well worthy of emulation, to towns many times larger. In doing this a municipality is in a position to make a definite proposition to a manufacturing concern and offer any inducements that the case may demand. For example, a firm treating with Port Arthur with a view to establishing an industry there will be able to figure to a nicety the cost, besides getting free land if such is contemplated, which is infinitely more satisfactory to the firm than if they had to deal with the municipality regarding water rates, taxes, etc., and then take up the question of suitable land location with private individuals. The efficiency of this method has been demonstrated and other towns will probably wake up and follow the same course.

INFORMATION FOR FOUNDRYMEN

AT the request of a number of our subscribers we propose starting a department devoted to the interests of the foundryman and dealing with the latest foundry practice. The foundry is one of the most important departments in a manufacturing establishment, and we feel that it has not received the consideration in our columns that its importance warrants. To make this department of the greatest possible practical value and benefit we have arranged with Mr. David Reid, of the Canadian Westinghouse Co., Hamilton, who is one of the foremost authorities on foundry practice in America, that he not only contribute but also keep in close touch with it. Mr. Reid will answer questions dealing with modern methods in the foundry or difficulties met with, and our readers interested in this phase of manufacture are freely invited to make use of the opportunity thus offered.

Ontario's Problem Regarding Niagara

Hon. Adam Beck Speaks at Guelph.

SPEAKING on the question of Niagara power, and its availability to Canadian municipalities, at Guelph recently, as reported by the Guelph Mercury, Mr. Beck stated that the Canadian side of Niagara Falls could economically supply heat, light and power to 1½ millions of Ontario's population of 2¼ millions, without impairing its scenic value or its value as a great advertisement for Canada. If the Government gave help in developing water powers in the north to bring out minerals, timber, pulp-wood, and agricultural products, it was equally justified in developing Niagara power to benefit the industrial centres of the south. The value of this power depended upon its cheapness—could it be developed and delivered at a price lower than that of steam? A number of enterprising municipalities, of whom Guelph was one, had co-operated in appointing a commission and contributing $15,000 to investigate the facts bearing on this question. The Government, seeing the great change that had come about in the values and uses of electric power, had supplemented their work by a second commission, and he believed the reports these commissions would present would be of some service to the people, even if it was not within their province to indicate to the municipalities how they should co-operate in getting the power. It had been demonstrated in South Africa and California that electric power could be transmitted long distances without much loss, and there was nothing mechanically to prevent the Government conveying electricity generated by water power to every part of the province. The Minister pointed out that the present Government, on assuming power, had cried "Halt!" to the Niagara power franchise giving; they realized that there was something valuable to be conserved for the people. He was free to confess that he believed the power could be brought to Guelph and other places at a low price, but if the people wanted it, they must demand it, as governments were not likely to move out of their ordinary course without strong public pressure.

Private Company Methods.

They could not get cheap Niagara power, he might tell them, if the companies handling the electric product were over-capitalized or their stock watered. Mr. Beck's judgment was that, in private hands, the making of electricity was done by one company, the transmission of power by a second, and the distribution of it by a third, but all three were one; the only use of three companies instead of one was to provide for more watered stock and greater profits at the expense of the consumer. The speaker also pointed out that the distribution of electrical power in any municipality was a natural monopoly. It did not matter whether they gave an exclusive franchise or not, it amounted to the same thing, and Mr. Beck spoke of their efforts to hold Brantford back from concluding a bargain for power with a private company. He also seriously doubted whether the competition of the power development companies at the Falls would result in low prices; he was inclined to look for a division of territory and a uniform price; the clauses against combining were valueless. Mr. Beck detailed the experience of Montreal city with the magnificent water powers of the St. Lawrence. At $40 per horse-power, the original charge, there was a great saving to the smaller power users in the use of electrical power, but one company gradually absorbed all the plants and franchises, raised the cost to $60 and $75 per horse-power and from 8c. to 14c. per kilowatt, and were now paying 7 per cent. on a capitalization of 24 millions, when the investment was only 7 millions. And when the power users protested against paying dividends on this watered stock they were met with the cry of interference with vested rights and of doing injustice to the widow and orphan and the honest investor who had bought the stock. Manufacturing firms are now combining to establish steam in that city, and Westmount, a suburb of Montreal, was establishing its own steam lighting plant, and that was all the benefit the cheaply produced electrical energy was to Montreal, for it was known that power was brought 90 miles from Shawinigan Falls and delivered at Montreal boundary at $15 per horse power, the monopoly distributing company then taking it in hand and selling it at $50 to $150 per horse-power. The people and the council of Montreal were to blame for granting such a franchise. Mr. Beck then went into detail on the conditions under which Niagara power was being transmitted by private companies to Buffalo, and showed how these were being duplicated in the transmission of power to Toronto. The development, transmission and distributing companies were all controlled by the same group of men—Pellatt, Mackenzie, Cox, etc. Instead of electric power being distributed to Buffalo at $15 to $20, it cost $31, and the city was talking about going back to steam for lighting. Buffalo, with 2,900 arc lights, paid $75 per light. What good was Niagara Falls power to the city of Buffalo?

Toronto, formerly paying $70, now paid $65 with steam power; Hamilton, with the cheaper power of the Cataract Power Company, using the city's streets and the people's canals, paid $80; London, with steam power, paid $76 per arc light. Outside the Deering and some large outside factories, which were brought to Hamilton by the low rate of electric power quoted to them, the smaller consumer and the people of Hamilton got no advantage from it. Hamilton, with electric power, paid 10c. and 15c. per kilowatt for electric lighting; Toronto, with steam power, paid 8c. and 12c.

Different Conditions Necessary.

There was then no prospect of cheap light and power for Ontario towns and cities from Niagara Falls unless under different conditions than obtained in the cities quoted. Mr. R. J. Fleming, manager of the Toronto Street Railway Company, told the News that the cost of Niagara Falls power wholesale would be $35 and $40 per horse-power; the transmission company charged $35 to deliver it. But they must remember always that the development company, the transmission company, the distributing company, and the largest consumers were all the same people. According to Mr. Fleming's statement Niagara power would not be delivered in Toronto at a price lower than steam power. Niagara power was a great boon; yes, but not at that price. Not the cost of production, but what the people would stand, regulated the price.

Mr. Beck was dubious as to any fair arrangements between the Governments of the United States and Great Britain as to the curtailment of power development at Niagara Falls to preserve the scenery. He was afraid the Americans would have already legislated for all the power they could use, and Canada would be shut out were power development stopped. Such a policy, too, would give a strong and immensely valuable monopoly to the present holders.

$19.50 Power for Guelph.

In the power development agreements it was stipulated that Canada should have the advantage of the lowest rate at which power was sold by the development companies to United States con-

sumers, and to the extent of half their production. Under these agreements power was being sold in 30,000 h.p. lots to the New York Central at $12 per horse-power at the Falls. Ontario users were entitled to that rate. Taking $12 as a basis the commission, which had been employing experts and engineers in investigating the problem, believed electric power could be delivered at Galt sub-station at $18 per horse-power, with the cost of local distribution added. That was not the cost price, but a price at which the power could be sold at a profit. The commission had found that in Berlin there were 29 firms using 1,595 horse-power who were prepared to pay $20 to $25 per horse-power for electric power. Berlin should get this, if a reasonable rate was charged for transmission over the $12 Falls rate, at $20, while the street railway people wanted to charge Toronto $35. In the Guelph district, on the same calculation, if the city of Guelph bought 2,500 horse-power, it should not cost more than $19 or $19.50 per metred horse-power.

Mr. Beck went into some technical information as to how prices of electric power varied, showing how, by storage batteries, overlapping, a company might buy 2,500 horse-power of 24 hours and sell 3,000 to 3,500 horse power of varying hours. The chief consumption of power was between 4 p.m. and 6 p.m. in Winter, when the lights were lit before the factories were closed. The cost of power would depend in Guelph largely on the economic adjustment of power to the needs of the several utilities. If Edison was successful in using cobalt instead of nickel for a storage battery, that would insure very cheap power in distribution.

Objections to Government Transmission.

Mr. Beck discussed objections which would be raised to Government transmission, viz., that some cheaper power such as produced gas or gasoline would be put in use; that the power might be transmitted without wires, and the right of way rendered useless, etc., but he did not lay much weight upon them. The water power cost nothing for fuel, coal was likely to get dearer, and if the right of way became valueless for transmission it could be used for other purposes. They had based all their calculations on buying a private right of way, but if arrangements could be made with the railways, and he believed that was quite feasible, to use their right of way for transmission lines it would greatly reduce the cost. In all new railway charters the Government had reserved the right to allow electric transmission lines on the rights of way. The Cataract Company used the G. T. R. lines, Mr. Yule interjected.

Nothing benefited and increased consumption more than cheapness, continued the Minister. Reduced prices brought greater demand. He believed in the possibility of transmitting power to Windsor and Sarnia at a price as low as the distributing company were paying in Toronto.

Importance to Manufacturers.

Mr. Beck dwelt on the immense importance to the manufacturers of Western Ontario of cheap power. They had the energy, the thrift, the capital, the climate, the facilities for transportation of raw material; none were better able to cope with business affairs, but yet much depended on the price of power. Winnipeg was providing 100,000 horse-power at $15 per horse-power, as against the $35 to $50 per horse-power asked in Ontario. The people of Winnipeg had refused Mackenzie & Mann the privilege of bringing in power for the street railway, which they owned; the people demanded that Mackenzie & Mann buy municipal power, and the railway people had appealed to the Legislature to compel the corporation to let in their power lines. In view of Winnipeg's power advantages, it behooved Western Ontario to wake up and act at once in the preservation of cheap Niagara power.

Benefits to Public Utilities.

Hon. Mr. Beck, in conclusion, spoke of the benefit of cheap power to a city owning as many public utilities as Guelph. He quoted the profits made in 1905 by Port Arthur, viz., $10,000 on her railway, $10,000 on her lighting, and $2,000 on her telephones, because of cheap power; her taxation had been reduced from 25 to 14 mills. Municipal and Government telephones were all right, but the power question was more important. A reduction of $15 per horse-power would mean a saving of $600,000 a year to Toronto, whereas the total telephone receipts were $400,000; the telephone benefited the few, while light and power helped the many. Mr. Beck eloquently pictured some of the advantages which cheaper power would bring in the way of extension of the benefits of cheaper and better public utilities to the common people: manufacturers, too, would be enabled to pay better wages. The fault lay with the people if they did not make these things possible.

M. P. Shea, who has become widely known to the trade, first as traveling salesman and later as advertising manager of the Canadian Fairbanks Co., Limited, has received another promotion and is now in charge of the gas engine department.

PERSONAL MENTION.

The Imperial Cement Co., of Owen Sound, have appointed as their manager Mr. H. W. Wood, formerly of the Owen Sound Portland Cement Co., Shallow Lake.

H. J. Fuller, president of the Canadian Fairbanks Co., Limited, has returned from an extended western trip, during which he visited the firm's branches at Toronto, Winnipeg and Vancouver. Like everyone else who goes west, Mr. Fuller is enthusiastic over business prospects there. He states that the demand for machinery and hardware supplies is increasing very rapidly in that part of the country.

* * *

In the Van of Progress.

To meet the requirements of their increasing business, Allis-Chalmers-Bullock, Limited, of Montreal, have made a number of additions to their sales organization. Among them is Mr. T. J Lynch, who has been appointed district manager at Toronto. He is already well known there, having for two years superintended on behalf of the Allis-Chalmers Company, Milwaukee, the construction of the fifteen million gallon pumping engine for the city of Toronto. Previous to that he was connected with the Metropolitan Waterworks and Sewage Commission of Boston. Under the new management they have entered upon an aggressive policy in the pursuit of business. They have leased a suite of offices in the new Traders' Bank sky-scraper in Toronto, added to their office staffs in New Glasgow and Winnipeg, and are

Steel King Indisposed.

It is doubtful if the illness or indisposition of any man in the United States could have a similar effect in the financial, industrial and mining world as that of Charles M. Schwab, president of the Bethlehem Steel Corporation, and interested in the Tonopah and Goldfield mining districts of Nevada to the extent of $5,000,000 or more. The capital stock and bonded indebtedness of the Bethlehem Steel Corporation is $53,851,000. Therefore, upon his good health and activity rests a good deal, as he has a large following in steel, iron and gold.

When the United States Steel Corporation was formed, Charles M. Schwab became one of the wealthiest men in the country, for he was paid $32,000,000 for his holdings in the properties that were gathered into the huge steel combination. Then he went into the shipbuilding scheme and succeeded in getting about all there was in sight. Many of the properties afterward were liquidated, and from this and other things there grew the Bethlehem Steel Corporation, upon which some $12,000,000 now is being spent in improvements of all sorts.

Tricks of the Trade.

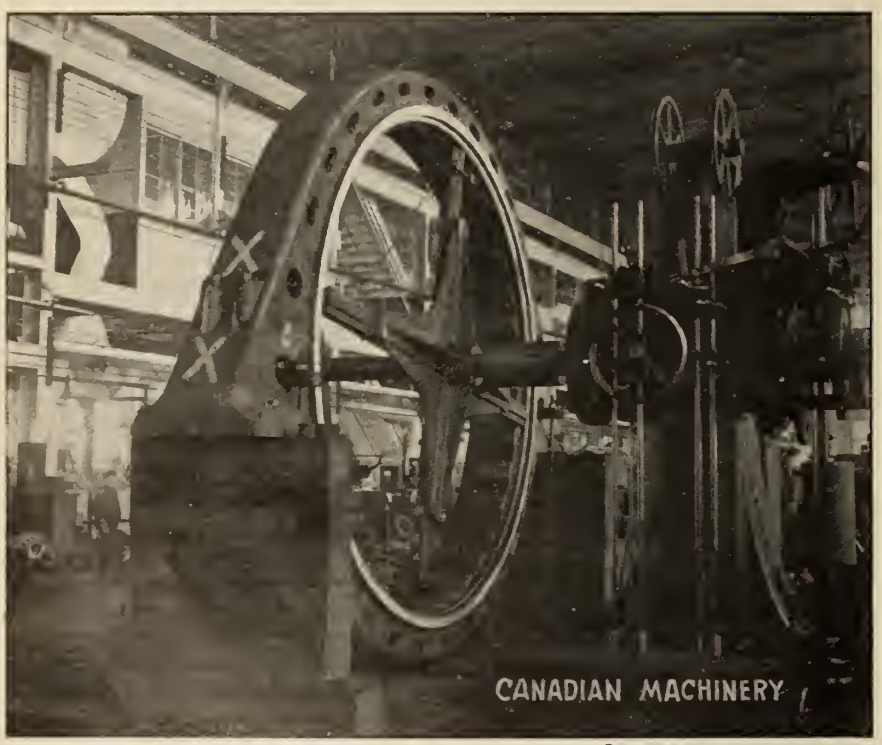
A Boring Job on a Miller.

TO meet the exigencies so frequently met with in all lines of business very often peculiar methods are resorted to. Such was the case of a large electric manufacturing concern here in Canada who had promised the shipment of a large alternator before the proper facilities for doing the machine work on it had been installed.

The machine in mention was a 500 k.w. alternator whose inside diameter was 10 feet 8½ inches. To necessitate the machining of the frame of this machine required a very large boring mill which though ordered had not yet been installed and as the shipment within a certain date was very necessary delay was avoided by doing the work as follows: The frame of the alternator was placed in an upright position on the surface table of a rotary miller (see illustration). The spindle of the miller was raised and set in a position directly in front of the centre of the alternator and was lengthened by an additional steel spindle 6 feet long and 6 inches in diameter which extended through the centre of the alternator frame and was supported at its extreme end by an upright standard upon which was held an adjustable journal into which the end of the spindle fitted. Upon the spindle was placed a four-armed web whose arms extended close to the bore of the alternator, and upon the end of each arm was placed a compound rest which held the bariny tools. The tools were fed through and back by means of the spindle feeds, which are of a large range. By means of the compound rest they were also enabled to fall off both sides of the bore. The diameter of the alternator being far beyond the capacity of the miller some difficulty was experienced at first in reducing the speed of the cutting tools, also the time required to do the work was somewhat longer than if it had been done with the proper facilities.

G. P. J.



Heavy Job for a Milling Machine

Competent vs. Incompetent.

Quite recently I met a representative of your valuable paper and agreed if anything turned up in my experience worthy of calling attention to in particular, to make a note of same and write up a little article to that effect, as Canadian Machinery was anxious to give its thousands of readers the benefit of practical knowledge from men in actual practice. The telephone rang. "Hello! Can you come down at once? Our engineer has made us a lot of trouble." So promising to be down at once, got ready and went and looked over the cause of the trouble. The engineer had gone away and forgotten to close the gauge cocks on the water glass, and they had burst the glass and let the water run out of the boiler; the plates were badly scorched and things in general were in a bad way. Then instead of draining the pipes, he disconnected the same upstairs and water flowed over sugar barrels and what not until emptied, then he found the drain valve and shortly after liberty to hunt another job. Mentioning his experience to another engineer, he said he never shut the valves on his engine or boiler as water might get in his cylinder and "bust the end out." He meant his cylinder head, but if his practice is continued of never shutting his gauge cocks at night as he said it would wear them out on the point, he may have the same opportunity of seeking some other employment he is better acquainted with.

Another case I may mention was the crosshead pin had sheared the pin which keeps it from revolving through the engineer having the brasses so tight, and coming up to me in the course of a few days after this occurred he told me he discovered the pin was going round and on investigating same found it had, necessitating the boring out of the crosshead and a new pin. "Now," said my unlearned friend, "the engine runs away and all I done was tighten up the strap." I may explain it was a ball flywheel type of governor and the combined strength of two men could not move the balls which ought to fly away from centre and cut off steam as the speed increased beyond its regular gait or recede to give more steam as the engine slackens from a heavy load being applied. Releasing the strap I said, "Open her up and let her go." The man in charge did so—I am not at liberty to call him the engineer—and after letting the engine gain her speed I told him to get me a plank until I applied a pressure on the fly wheel. "Oh, no," he said, "I daren't leave her; she'll run away," so after assuring him of no immediate danger, and that I would hold her with the plank, he secured one twice as long as necessary, and everything has been all right since. Now it seems if there is an inspector about he never puts any of the so-called engineer through a course of sprouts to find out if he is running the engine or the engine running him, so the danger of putting such men in charge of steam plants is evident enough without further elaborating. These events have all happened in the course of a few months and the men engaged were raw recruits. The facts herein contained may be verified any time and the cost to the firms mentioned approximated $300 for these oversights by unskilled, incompetent men in charge, and on an average would pay for qualified men. WITNESS.

Mechanical Reviews

OPINIONS AND STUDIES WORTH NOTING

SHOP TOOLS AND DEVICES.

FOR rectifying work which has been threaded with a solid die and which has as a result a thread not true with the body, as exaggerated at (A) Fig. 1, I use a piece (B) in a spring chuck in a bench lathe, or other lathe, and hold the piece by the thread while turning and facing (as indicated by the dotted lines) to true the job with the screw. I carry pieces like (B) for screws in common use, for various purposes as I have shown in other articles. The thread and outside run true, and the lock-screw (C) bearing on (A) with a point, holds the screw by the sides of the threads, a centre being obtained also if needed.

A method of coiling heavy spring wire on a light arbor is illustrated in Fig. 2. The piece (D) is held in a chuck or collet in the tail stock of the lathe, and drawn back as the spring is coiled, thus supporting the arbor (E) at the bend of the wire. I recently wound in this way piano-wire springs of the dimensions given on the sketch.

Fig. 3 shows how a pair of milling cutters can shave down the sides of a thin tapering piece, such as a watch regulator, by being made to work against each other, and give a draw cut. The teeth as shown at (F) being on a tangent, strike the work gradually and two or three at once. (G) shows the manner of clamping the work. ...

Figs. 4 and 5 are old-time devices for rocker filing such pieces as are shown in these two sketches and in Fig. 6. Flat filing is easily done in this way.

The holder in Fig. 7 is for turning flat work like (H), say a counter bore or reamer blade. The only novelty in the device is the slot (I), sawed in from the end, which obviates the difficulty of filing out a slot for the blade, the nut (K) making a solid job. By slotting two pieces like (H) in the centre half way across, and interlocking them, they can be inserted in right angle slots where the size of the arbor will admit, and so form a four-lip reamer, or a tap all fluted.

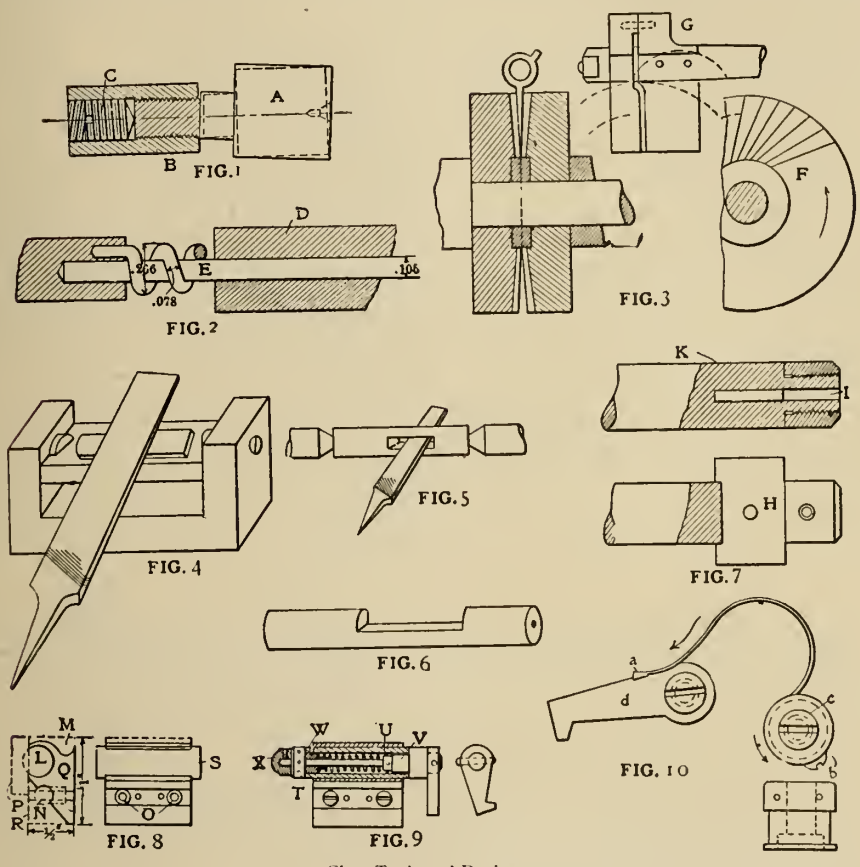
By the way, a tap can be cut readily in a lathe, and cut without tearing, by cutting it somewhere near size first, then milling the flutes, annealing the steel, and cutting the thread to size last. This helps in the hardening, too, as it takes the warp out of the steel.

Figs. 8 and 9 cover several points of interest. The first illustrates how a very neat pawl-bracket was made in a bench lathe and mostly with twist drills. The material was mild steel 1x½ inch, sawed off in the power hack saw. The holes (L,M,N,O,O). were drilled, as shown by dotted lines. The extension (P) was clamped to (Q) to facilitate drilling (L). The corner (R) was sawed off by hand. The sleeve (S) was soldered into (L) and a file completed the piece. Fig. 9 shows the pawl mechanism, which is lively and has a great range of adjustment. The spiral spring is soldered at the ends to collars (T) and (U), the latter locking the arbor for the pawl at (V). By turning (T) by the pinholes to get the tension on the spring, and locking it with the screw (W), entering depressions in (T), the pawl is given any pressure needed (X) is merely a retaining collar.

In Fig. 10 is shown another adjustable pawl spring, a flat one with edges turned down at (a) to keep it in place. By turning the stud (b) and securing it with the screw (c), the spring is moved in the direction shown by the arrow to increase the tension. The spring as constructed is almost unbreakable.

This pawl was used in an index with eight divisions. It carried the index plate two places, then a retaining pawl held the index while the pawl (d) moved back a notch. Then the retaining pawl came out and the pawl (b) drew the index back one space; thus the pawl moved two spaces each time and still gave eight divisions. The spring as arranged was easily adjusted to give the pawl the right pressure on the index to draw it back while overcoming the friction of a thin cup-spring against it.

Some of this matter may come in handy in model and experimental work or in machine construction.—American Machinist.

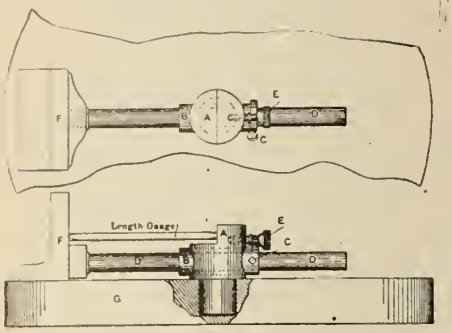


Shop Tools and Devices.

WORK SETTING TOOL FOR LATHE AND BORING MILLS.

THE cuts show the device and its use in setting up the angle plate, (F), and the same method of use applies when chucking a piece of work off centre. The central pin, (A), which

fits the centre of the table is bored at right angles to receive the sleeve, (B). This sleeve is provided with a setscrew, (C), and a lug on the upper side for the milled head adjusting screw, (E),



Work Setting Tool for Lathe and Boring Mill

The rod (D) is fitted in (B) and one side is flattened for the setscrew, (C). In use the adjustment is first obtained by sliding the rod (D) to its approximate location, where it is locked by the setscrew, the final adjustment being gotten by the adjusting screw, (E). The lower sketch also shows how a length gauge may be used in connection with the device, a shoulder being provided on the upper end of (A) whose face passes through the centre of the table. It is, of course, necessary that the shank of the device fit the boring table hole closely.—Mechanical World.

HOW TO BALANCE PULLEYS.

IT is surprising to note how an otherwise capable mechanic goes about the seemingly simple process of balancing pulleys and other revolving parts. I saw a first-class machinist place an 8-foot section of line shafting, which had several pulleys on it, be-

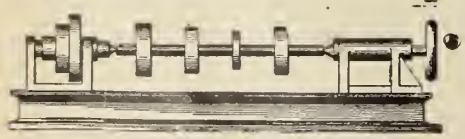


FIG. 1.—WRONG WAY.

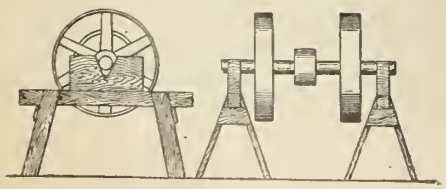

FIG. 2.—ANOTHER WRONG WAY.

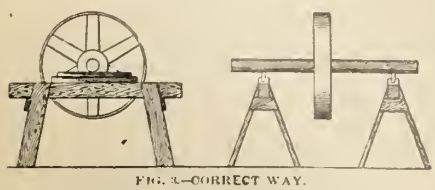

FIG. 3.—CORRECT WAY.

How to Balance Pulleys.

tween centres in a lathe, to balance it, after the manner shown in Fig. 1. Of course he failed, and the job had to be done by somebody else.

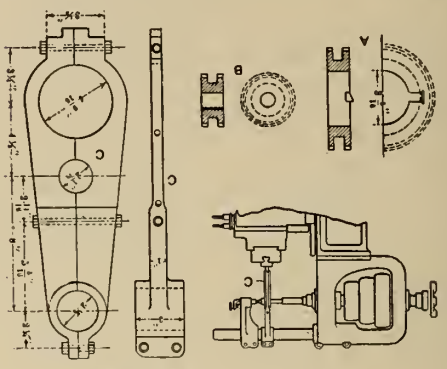
Another machinist, who ranked very high, did something even more incongruous. A countershaft with three pulleys on it, was brought into the shop to be balanced. The man got two V-shaped blocks, set them level and dropped the ends of the shaft into the grooves, as shown in Fig. 2. The foreman ordered the shaft removed from the V-blocks, but the man did not take any of the pulleys off the shaft, but tried to balance them all together, so the work had to be done over by another workman.

Every engineer would do well to have in his tool box two steel straightedges, about 15x1¼x¼ inches. These can be let into wood and placed on blocks or horses which have been leveled especially for balancing work, as shown in Fig. 3. Only one pulley should be put on the shaft at a time, as it is impossible to balance more than one pulley at once.

Balancing a very wide pulley, or a drum, presents a very difficult problem, and it is hard to find which end is out of balance. I have seen drums 3 feet long run in loose bearings very rapidly, while chalk was held to the shaft to mark the side which was thrown out of true by centrifugal force. The heaviest part of the rim being shown in this manner, weights were added to the opposite side to effect a balance. Theoretically, when a revolving body is in balance, every part is balanced. That is, if any number of sections were cut through it at right angles to the centre, or line of revolution, no matter how closely together, each section should balance. Of course, this condition is almost impossible in practice.—J. P. H., in Power.

TOOL FOR TURNING WRIST PINS AND TUMBLING SHAFTS.

AN interesting special tool for turning wrist-pins, tumbling shafts, etc., is the design of Mr. John Tonge, master mechanic and master car builder of the Minneapolis & St. Paul Railroad at Minneapolis, Minn. It is used on the milling machine or lathe according to the class of work. The wrist-pins of four bar guide crossheads are turned on the milling machine with this device, as shown in the accompanying cut. Of course on a job like a crosshead or any other job having shoulders which prevent sufficient overtravel of the tool, the tool must be set twice in order to finish the surface. The device consists of a frame, (C), split on its centre line in two parts, which are solidly secured as one when in operation, by bolts at the centre and ends. The smaller end of the frame is secured to the arm of the milling machine, and the centre hole is brought in line with the machine arbor which passes through it, and the pinion, (B), is splined to the arbor. This pinion meshes into a gear, (A), which is made in halves and fits

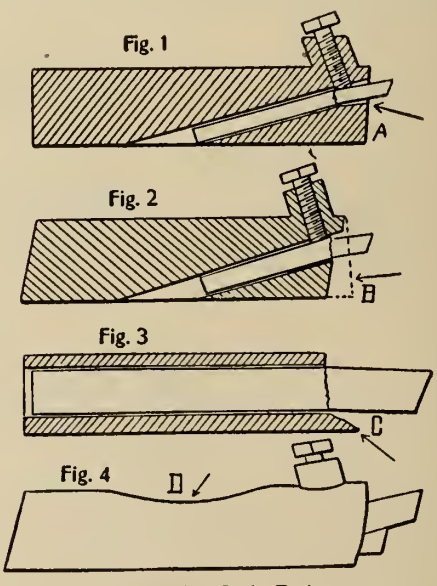


Milling Machine Attachment.

the larger hole in the frame. Both of these gears are grooved to fit the frame in which they work and cannot therefore leave their respective positions. The larger gear has an internal diameter large enough to clear the largest wrist-pin, and is fitted with a cutter by which the turning is done. The motion imparted to the pinion by the arbor is communicated to the gear which in turn drives the tool. When used on the lathe for turning tumbling shaft bearings a gear is screwed on the spindle in place of the faceplate and this meshes in a pinion mounted on a short splined shaft which drives the pinion (B) in the same manner as the spindle of the milling machine.—Railway Master Mechanic.

READY-MADE LATHE TOOL.

OLD mechanics looking back over their history as such can remember the days before the patent lathe tools. In those days they were



Ready-Made Lathe Tool.

obliged to forge their own tools into the desired shape. Modern improved tools can be ground to any desired shape and used in most any position.

Their use, however, requires a certain amount of judgment.

Fig. 1 shows the effects on a small tool used for too heavy duty. This tool was made for a 12 or 15-in. lathe, but was used in a 30-in. lathe. The bottom at (A) is worn away until the pressure of the screw breaks the steel.

Fig. 2 shows the effect of grinding without removing the steel. The under support is completely ground away at (B). Fig. 3 shows a cutting-off tool allowed to hog in and break, battering down the support, (C). Fig. 4 shows the effect on a small tool which was used in a large lathe. The powerful screw mashed the tool at (D).

I recently looked over a number of patent tools of different makes. They had been used about one year and were a sad looking pile of junk. A lack of good judgment had sent them to the scrap heap.—Popular Mechanics.

JACKS FOR PUMP PIPES.

IN Fig. 1 is shown a jack and its parts in detail for holding pipe. The jack may be made of either $1\frac{3}{4}$ in. by $\frac{1}{2}$ in. steel, very good iron tire or of $1\frac{1}{8}$ in. square axle stubs taken from an old carriage axle.

The hook or claw which holds the pipe is shown at (A), and a side view of it, showing the manner of forging so as to strengthen it at (H), where a hole is drilled to receive a $\frac{5}{8}$ or $\frac{3}{4}$ in. rivet, is shown at (C). This claw is made for $1\frac{1}{4}$-in. pump pipe, the size most commonly used. The lever and rest is shown at (B). It should be curved in the arm so that when in use the hook cannot touch the platform to loosen the hold on the pipe. (D) shows a top view of (B). The hole (I), in the lever, (B), is for receiving a chain or rope when using the tool over an old-fashioned well or cistern, and prevents the tool from falling in and being lost. The rivet holding the parts together should be strong and fit like that in a pair of tongs. The tool opens and closes by lifting away from (E).

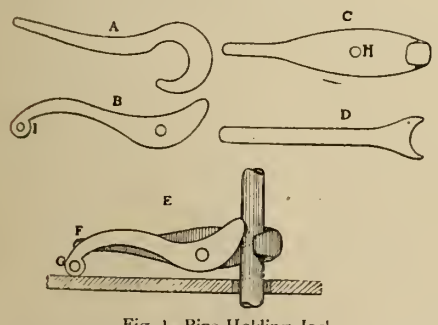


Fig. 1—Pipe Holding Jack.

For lifting and lowering pump pipes a tool like the one shown at (X) is satisfactory. It may be used either with a rope or by passing a bar or hand spike through the ring, so that two men can lift on it. It is made of $1\frac{1}{8}$-in. axle stub of square stock, the opening being just large enough to let the pipe into the hole of the tool which should be but $\frac{1}{8}$ in. larger than the pipe. This tool is shown in use at Z.

A tool for hand use is shown at (Y), and it may be used singly or in pairs. The ring at the end provides hand-hold and it is turned out of the handle solid, just like a poker hand-hold. The light part should be $\frac{3}{4}$ or $\frac{7}{8}$ in. round and the rest of $1\frac{1}{8}$ in. square. A set of these tools should comprise a jack as at (E), rope and a lift like (X), or a jack and two hand lifts like (Y).—American Blacksmith.

STARTING A GAS ENGINE.

THIS is the question that comes up many times in the mind of the young engineer, when he finds out after a number of fruitless efforts to "get her started," that she will not turn her wheels or "go." Now there is a reason for this condition of affairs

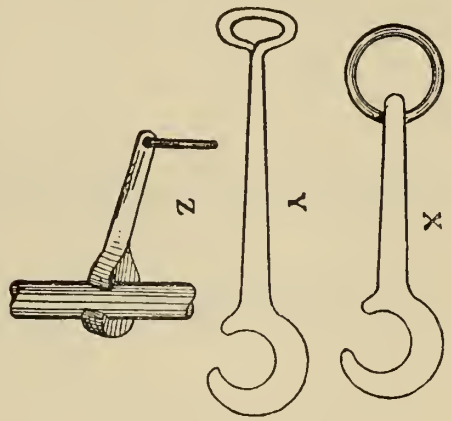

Fig. 2—Pipe Lifting Jack.

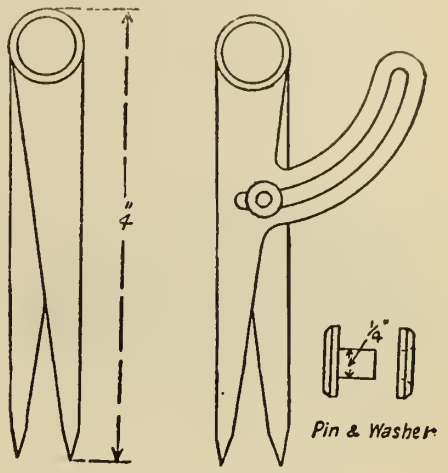
when the gas engine refuses to obey the behest of the driver, and I propose in this article to give such plain instructions that the novice may be assisted in starting the gasoline engine. In the first place see that the compression is right, that the admission valve is tight and will admit only enough of the mixture (gasoline and air) to make a charge that will take fire from the sparker and move the piston forward. In the next place see that the sparker is clean and will make a bright spark at white heat when the contact is broken, and at the right time. And right here I want to say to you what "in time" means to go if everything else is right, and "out of time" means to not go even if everything else is all right. The valves of the engine must be kept well ground down with emery and oil so as to preclude a possible leak, for this will very seriously weaken the power of the engine even after it is started. The spark must be made when the connecting rod of the engine is on the "up stroke," with the crank-shaft about three inches below the horizontal line of the centre of the cylinder, and herein lies the whole secret of the greatest efficiency from the least amount of gasoline. As there is an interval of time after the spark is made until it ignites the charge, it is very evident that the movement of the machinery continues and the moment of ignition should take place when the compression is greatest, and this will be when the piston is on its farthest "in stroke," i.e., in perfect line with the centre of the cylinder. But if the charge be ignited at this point the engine will not develop the greatest power, as the interval spoken of will elapse and the piston will have started on its "out stroke," thereby not getting its full force of the expansive gases, liberated by combustion of the air and gasoline.

Therefore, it will readily be seen that we must allow for the interval spoken of if we would get full returns for the energy we use in propelling the motor. I have tried to make this plain and very easy to understand, and I hope my efforts will help out some experienced or inexperienced gasoline engineer, who has trouble with his engine, either in starting or developing the power at which it is rated.—The Gas Engine.



Compasses for Metal Work.

COMPASSES FOR METAL WORK.

THE compass shown at Fig. 1 can be made by most any one out of sheet material. The compass has no locking device, as it depends on the tightness of the point to keep it in position when in use. Use thicker material than is used for calipers, says the Model Engineer, London, and harden and temper the points. Fig. 2 shows another useful form of compass which is not difficult to make.

Milling Cutters; How They are Made, Used and Abused.

By John Edgar.

CUTTERS form a very important item in modern milling practice. Much of the success attained with the milling machine is dependent on them. Cutters, to give satisfactory results must be particularly suited to the work they are to perform. They must be properly designed and be made of only the best of material. None but poor results may be expected when not skillfully handled.

Fig. 1.

It is the purpose in this series to show the different styles, how they are made, how they may be used to the best advantage and how they are commonly abused.

Milling cutters may be divided into three great classes., the first of these being the plain cutters, sometimes called surface, axial or slab milling cutters. The latter term being applied to designate the cutters used on the heavy planer type machines.

The second class are those known as face mills, which may be again subdivided into two sub-classes as: side mills and end mills.

The third class comprises cutters which are made to mill a form such as gear-cutters, tap and reamer cutters, etc. They are made in two styles, those which are made with milled teeth as an ordinary plain cutter called "form mills," and those whose teeth are formed in a special forming machine, and whose shape is retained throughout their life are called "formed cutters."

The dividing line between any two classes may be straddled by any single cutter, so that it is hard to decide which class it really belongs to.

For the benefit of those whose knowledge of milling machines and their accessories is limited, it is the intention in introducing the half-tone, Fig. 1, to familiarize them as much as possible with the different styles before going further into the real object of the articles.

The cutters shown in group (a) are the simplest cutters used on a milling machine. These are plain milling cutters. When this style cutter exceeds three-quarters or one inch in length, they are made with spiral teeth, that is, the cutting edges are given a twist. It is claimed that this reduces the power necessary to pull the cut, they are less liable to chatter and will therefore produce a much better surface. These cutters are then called "plain spiral mills," examples of which are shown at (b).

When a large amount of stock is to be removed, that is, when the depth of cut is great, the teeth are made much coarser and are "nicked," giving a cutting edge, which is not continuous across the face of the cutter, but is divided up into a number of short cutting lengths, each separated by a nick, the nicks on one tooth being staggered to those on the preceding and following (c). This style cutter will remove a given amount of stock with the least possible expenditure of power and much faster feeds may be used than with the plain mills.

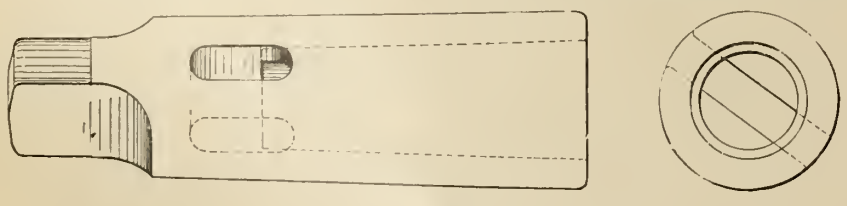


Fig 2.

Another form of plain mill is that shown at (d). Those are called metal slitting saws, and vary in thickness from one-sixteenth to a quarter inch, and in diameter from two and a half inches to twenty inches, and larger. Saws thinner than one-sixteenth inch are called screw slotting saws and are generally made to correspond to some sheet metal gauge number in thickness.

The cutter shown at (e) is a side milling cutter belonging to the second class tooth, as will be seen in the example at mentioned above. As will be seen, this cutter has teeth cut on its sides as well as on the periphery. It is made to be used on a shank to which it is keyed and held in place by a nut screwed on the end of the shank. This style cutter is more properly called a face mill. To the rear of this cutter is seen a large inserted tooth face mill. In this case the cutter is large enough in diameter to permit of a large hole to fit on the threaded end of the machine spindle, and is therefore provided with a threaded hole. The body of the cutter is made of cast iron and the blades of cast steel. When particularly hard service is required of this style cutter it is better to use some good quality of self-hardening, high speed tool steel for the teeth, as they will wear longer and require less sharpening and will permit of much higher speeds and faster feeds than the ordinary grade tool steels.

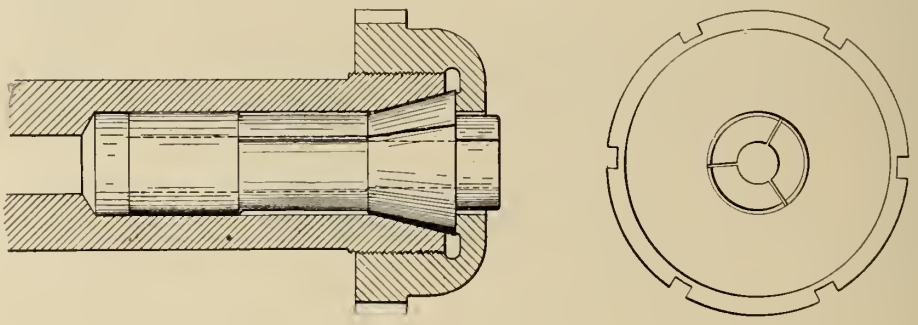

Fig. 3.

Sometimes it is desired to finish both sides and bottom of a deep groove with a milling cutter. One method of doing this would be to use a side milling cutter with teeth cut on both sides and periphery. Such a cutter is shown to the left of the large face mill.

Another method of finishing the groove

would be to use an end mill, in which case the centre line of the spindle would coincide with the centre line of the groove and be perpendicular to the bottom of same. Four end mills are shown to the rear of the group (a).

These end mills have straight shanks spotted so that they may be held in a simple collet and secured in place by means of a set-screw. For many purposes it would be best to have the shanks made to some standard taper, such as the Morse or Brown & Sharpe. The latter is the recognized standard among milling machine manufacturers. The taper need not necessarily be as large as that of the hole in the spindle, but is generally made to correspond to the size of the mill itself. In use this mill is inserted in a reducing collet, the outside of which is made to fit the spindle and the inside to fit the shank of the mill. Such a collet is illustrated in Fig. 2.

When the mills become so small in diameter that it is no longer practical to make them with taper shanks, they are made with straight shanks, and in such cases are usually held in a spring collet, the most familiar form being like that shown in Fig. 3. This collet consists of three parts, the body or shank, the split bushing and the ring. The bushing is provided with a hole to fit the shank of the mill, a separate bushing being necessary for each size shank. The outside of the bushing is made with a conical head, which fits into a conical seat in the shank, and, being split, contracts on being forced home by the threaded ring, thus binding on the shank of the mill, keeping it from turning or working loose. This is the most successful method of holding straight shank mills, as it holds them sufficiently tight for most purposes and will always run true if properly made.

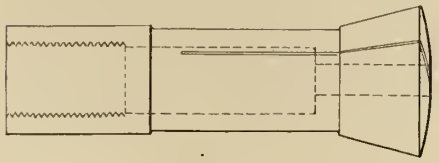

Fig. 4.

The Becker-Brainard Milling Machine Co. have incorporated this idea in the smaller sizes of their vertical machines by making the spindle of the machine with a conical opening. They use it as the body part of the arrangement mentioned above and provide a collet like Fig. 4, that corresponds to the bushing above, which is drawn back into the taper by a draw-bar, making a very simple and handy method for holding the small end mills which are used so extensively in these machines.

Going back to the half-tone, we will find at the extreme left in the foreground, examples of a special form of side milling cutter. These are angular milling cutters such as are used in making cutters.

On the right we have cutters which will be recognized as belonging to the third class. The cutter shown at (f) being a "form mill," since the shape must be followed in sharpening, while that at (g) may be sharpened by simply grinding the face of the tooth, is called a "formed cutter."

We will next treat the matter of selecting the proper style cutter for different work and give some points that may help in the design of same.

The design of milling cutters must depend to a certain extent on the purpose for which they are to be used, but we may give a few rules which will apply to most cases and be useful in all cases, though they may require a certain modification in their application.

In making cutters, much depends on the facilities at hand for milling and hardening same. A cutter might be made a certain way to a great advantage, but would be very difficult to harden, so that modifications, while they show a loss of efficiency, must be made in order to be successful.

Designing a Wood-Working Molder

By T. C. Robertson.

ARTICLE III.

Arrangement of Feed Rolls.

ARRANGING feed rolls and cutterheads forms an important feature in molder design as regards convenience of operation coupled with rigid construction. The accompanying sketch (Fig. 1) shows a recent construction of feed rolls which will be appreciated by mill men. The rolls in table are so arranged as to be interchangeable with top rolls, which are usually corrugated. It often occurs that moldings have to be made of dressed lumber that is already scant in thickness, and if the operator desire to finish face side up and a light cut is to be taken off, the corrugated rolls might mark the material too deep to be taken out. To avoid any trouble in this direction they may be placed in table and smooth rolls put on top. These rolls when placed in position should be slightly inclined so as to lead material being fed to hug tightly against fence in passing through. They should also be carefully adjusted in relation to top of table, for if too

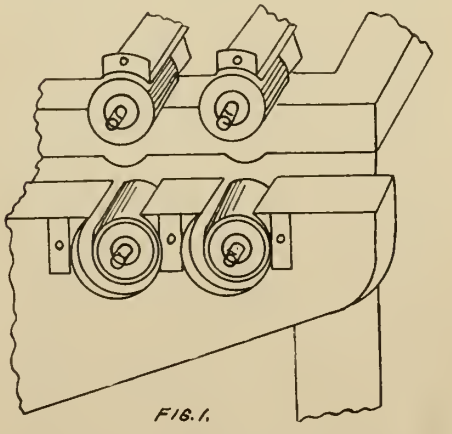

FIG. 1.

high it will cause wavy work owing to material not resting firmly on table.

While we have under consideration the location of feed rolls it might not be out of place to suggest what might be considered an improvement by some on what is known as outside molders, that is to provide in construction of machine a delivery or feeding out roll which for ordinary matching would prove a great convenience, besides adding very much to feeding power of machine. It might be possible to so arrange these rolls that they could be removed if in the way of doing certain kinds of work.

Position of Cutter Head.

The bottom cutter head may be placed either before or after top cutter head, or one on either side, according to design of molder. Both positions have strong advocates from operators and both have their peculiar advantages according to method of finish adopted. In any case provision must be made for using long knives, causing a throat piece to be placed in table which must be made adjustable to and form

head so as to act as a chip breaker for any diameter of cut. This requires to be done quickly and firmly, and if possible to leave the table in as smooth condition as necessary. The usual method of doing this has been to fasten with screws from top countersunk below table, leaving an uneven surface. By referring to sketch (Fig. 3) a method is shown by which throat is clamped firmly and quickly in any position by means of a cam and lever connection, leaving a smooth and even table which is appreciated by operators desiring to do fine work.

By referring to sketch (Fig. 2) a method is shown by which bottom cutter head is drawn out from its position in table, allowing freedom in setting and sharpening knives, also a slide by which the head and its connections may be adjusted vertically. When bottom cutter head is placed after top head provision should be made to swing projecting part of table out, exposing cutter head for convenience in adjusting and sharpening knives.

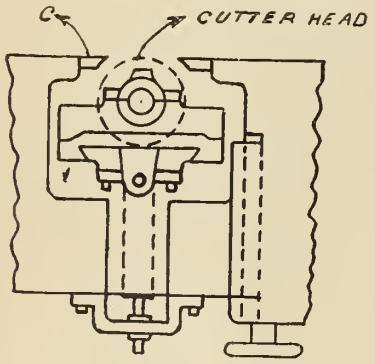

FIG. 2.

The top cutter head should be mounted upon a heavy shaft contained in a yoke which should be adjusted horizontally and provided with a removable outside bearing, which is necessary in removing head. A new feature in driving this head consists in double belting one pulley in centre of yoke and one on outside. To the writer this additional belt seems necessary only when a large amount of stock requires to be removed and should be avoided if possible, owing to space occupied. A better construction might be larger pulleys and double belt on inside of yoke carrying the head.

Other Features.

The shoe or chip breaker in connection with top head should be so pivoted as to swing as near as possible in line with circle of cutter head and have adjustment to and from head for different lengths of knives. It should also have detachable piece giving further adjustment and permit of applying special shoe pieces. A feature on this detachable piece which has recently been introduced is to provide steel sections of different widths which are made interchangable in case of uneven wear, the steel also insuring a longer period of wear than cast iron. The entire shoe is weighted and is so arranged that it can be easily pushed back out of the way.

The pressure bars in connection with side heads when bottom head cuts first can be so designed as to act with much greater efficiency than when bottom head cuts last. Room is obtained to have horizontal as well as vertical adjustment. Pieces of any shape can be applied and located in any position upon bar within the limit of cut of heads. These pressure bars can be so designed as to throw entirely out of way to facilitate adjustments on side heads.

These notes upon molder design have been but fragmentary, the aim being to call attention to some of the recent developments which have a bearing upon those interested in their operation and construction. It is a fallacy to suppose that the builders of these machines originate the valuable improvements which from time to time are developed. They are indebted to the operators of these machines, who are in a position to find out the weak points and make suggestions for improvements. In fact in all lines of machine development the designer is indebted to the operator for his most valuable contributions which come to him in such a way that credit is not always placed where it belongs. These notes upon molder design apply to what is known as outside molders. The inside molder is adapted to a more limited class of work more closely allied to standard planing and matching machines.

LIFE SAVING DEVICES OF A MODERN FACTORY.

By J. G. L.

In very few lines of manufacturing are the possibilities for accidents so great as in a plant turning out tinware in large quantities. Some years ago, in the largest manufactories of this kind, the day which passed without a serious accident was almost phenomenal.

Recent advances in mechanical science, however, have wrought such a revolution that these are now comparatively infrequent, and not so serious as formerly.

A special study of this problem of reducing accidents has led the Thos. Davidson Manufacturing Co. to adopt some very considerable precautions in their large plant at Montreal. The entire plant is kept scrupulously clean. All employes are expected to eat their lunch in the club rooms, where tea, coffee and milk may be obtained at the moderate charge of two cents per cup, and during the noon hour the entire factory is aired and ventilated so as to be in a sanitary condition for the rest of the day.

The club rooms referred to are maintained by the Employes' Benefit Society in connection with the company, which enjoys a membership of over one thousand people. The society employes a doctor to treat all members who are ill, and also provides for "sick pay" in the case of employes who have been with the firm six months or more.

In a convenient corner of the factory is a small surgery where the easier cases are treated. A better equipped surgery is located in the club and here the more serious injuries are attended to. The majority of such are treated by a medical attendant who is a member of the staff, but, where amputation is necessary a surgeon is called in, or the patient sent to the hospital.

The ponderous presses which make the innumerable fittings required for all the products of such a plant, are responsible for most of the accidents,

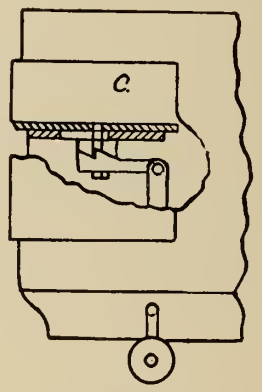

FIG. 3

though there are occasional cases of severe burns, in the tinning and galvanizing rooms. Up to a comparatively short time ago, the most dangerous machine in the factory was that which cut the centres from screw tops intended for gem jars. This was done by putting the tops in singly, so that the operators frequently lost fingers in placing or removing the article. Now, however, a rotary centering machine is used, and injuries are rendered impossible. The operator places the tops in holders fitted to a revolving disc, and when the holder reaches a certain place, the press descends and cuts out the centres.

In connection with the operation of turning out the gem tops, two other machines are utilized, which are of great interest because they replace older machines entailing great danger in handling.

The visitor to this plant cannot fail to be impressed with the precautions taken everywhere in protection of employes. Indeed, it is considered to be a model one in this respect.

Foundry Facings

The Trade in General.

BECAUSE the foundryman labors and sweats, toils amid sand and dust, gas and smoke, and emerges therefrom sooty and grimy and soiled, indicating clearly that he is not on the road to a five o'clock tea party, and, moreover, because popular opinion regarding him as a factor in manufacture has been at fault, the shaper of molten metal has not been conceded the position due him in view of his importance in the industrial world. The manufacturing costs of many lines have their start in the foundry and every manufacturer knows, who has a foundry in connection with his plant, that to economies effected here in recent years is due in some measure the lessened cost of production.

While the art of molding antedates most trades by centuries, the foundryman has until recently shared but few of the working comforts that modern progress has adapted to other artisans. Any old corner was considered good enough for the foundry, and the constitutions of the workers therein were supposed to be proof against what would put an ordinary mortal out of business in a few weeks. This condition of affairs was accepted as a natural inheritance and little complaint made. A man naturally partakes to some extent of his surroundings, and in the dark and gloomy atmosphere that was recently characteristic of many molding shops it was but human nature asserting itself to find the men lacking somewhat in ambition to probe deeply into the science of their trade.

A change for the better is manifesting itself on all sides. Foundries that once were dim and dismal are now bright and attractive. Labor-saving devices of all kinds have been introduced, making the trade less one of drudgery. The effect is evident in the men themselves. They are brighter, more cheerful, more active, more intelligent, and more anxious to learn. This does not infer that the men have not been intelligent or anxious to learn, but that with a change of conditions a sense of individual broadening and expansion has been experienced.

It is hoped that this is but the beginning of a much higher awakening among the foundrymen, and that not one of them will be content until he has at least gained a fundamental knowledge of chemistry and metallurgy, in doing which he will find an added interest in his work and make his services of more value not only to himself but to the firm with which he is engaged.

Top of the Trade.

SEEMINGLY few of those engaged at the foundry trade have realized the possibilities ahead of them, and which need but a certain definite application and ambition to make the possessor of that trade one of the most indispensable factors in the industrial world. The average foundryman has never realized that to become a metallurgist is his natural field, and having a theoretical knowledge that enables him to analyze his materials places him on an altogether different footing being more capable of understanding the different actions and reactions and of knowing definitely, without the shadow of a doubt, the exact requirements of the case. One of the few who have upheld the standard in this direction is

David Reid, Hamilton
President Associated Foundry Foremen of America.

Mr. David Reid, of the Canadian Westinghouse Co., Hamilton, Canada, president of the Associated Foundry Foremen of America.

Mr. Reid is a Scotchman, having been born in Glasgow, coming to America with his parents and settling in Worcester, Mass. He took a special high school course with a view to becoming a civil engineer. This idea was dropped, however, and Mr. Reid entered the foundry instead. About a year after this, on returning from work one day, grimy from the result of honest labor, he met a former high school teacher who lamented that the young molder had taken such a step, and intimated that he was throwing his life away. He realized, however, what has already been mentioned, that there was lots of room for a man who wished to know the why and the wherefore or the causes and different effects in connection with this, one of the oldest of the mechanical arts.

At the end of three years he went to Connecticut to get an insight into tool machinery, afterwards returning to the Holyoke Machinery Co. as leading hand on their heavy work, aiding the foreman in getting up the rigging for all classes of work, and putting in a great many hours experimenting and studying in his own time without extra pay. Later an opening occurred in the Builders' Iron Foundry, Providence, R.I., in the gun room, and here he spent about five years on heavy engine and Government work. The foreman in this works selected him as a specialist to start the heavy work in a new foundry of Howard & Bullough Co., of Pawtucket, where, after about two years of strenuous work, his health broke down and he was ordered home to Scotland.

Even when on pleasure bent he found time to put in some practical work in the Old Country, particularly marine work, and in Dundee was offered the position of foreman, which was refused to return to the United States. On returning Mr. Reid became a leading hand in the Corliss Engine Works, Providence, R.I., and from there to the foremanship of Saco & Ritter, later becoming manager. By introducing modern methods here, such as molding machines, and dividing the labor, whereby the molder practiced the art of molding and nothing else, the melt was increased from 12 or 15 tons daily to between 50 and 60 tons.

Not being satisfied with his knowledge of metals at this time, Mr. Reid arranged for a course in chemistry and metallurgy with the Boston Testing Laboratory, under Prof. Saveur, of Harvard. The determination of the man is shown from the fact that for nearly a year he left at 2.40 a.m. on Saturday, traveled 100 miles to Boston and worked all day in the laboratory, after which a couple of hours' rest and he worked till midnight. On Sunday he started at 7 a.m., taking a lunch with him and remained there until 5, after which he took the train, arriving home at 10 p.m. To get closer to the iron industry he resigned his position to accept the superintendency of the Howard & Bullough's American Machine Co. A flattering offer from the Rarig Engineering Co., Columbus, Ohio, took him to

this place, where he was engaged principally in Government work. From there he became associated with the Westinghouse Co., which led up to his present position of superintendent of the foundry department in the Canadian Westinghouse Co.

Besides the above mentioned practical experience, Mr. Reid is a member of the American Society for Testing Materials and a member of the committee for two years on getting up standard specifications for castings and cast iron, as well as a member of the American Foundrymen's Association and the Associated Foundry Foremen. Mr. Reid has risen to his present position as one of the most prominent foundrymen of America through well-directed, intelligent effort and proper realization of the possibilities. He is an authority on many branches of the foundryman's art. Many of the readers of Canadian Machinery will be glad to know that arrangements have been made with Mr. Reid whereby he will contribute practical articles on foundry practice from time to time, and will answer any questions dealing with foundry practice that may be sent in to this office.

A Foundry Kink.

I came across a little kink in the foundry the other day. A hand wheel was brought in. A broken-down job I thought; it looked like it. The rim, hub and four pieces of the arms were there. The hub was broken in two, but that did not matter as much as the loss of the arms. It was a hand wheel, of the same style that is used on the tail stock of a lathe. The hub was about 4 in. above the rim. To put in six arms all the same without the pattern was the problem. The wheel was about 18 in. in diameter, so the workman got a 24 in. flask, put down the bottom board with the parts of the wheel on it, and bedded it in. Then he made the joint of the three arms on one side of the flask. There was a centre bar in the flask that came down near the joint. This one side of the flask was rammed up, lifted off, the pattern drawn and turned around with the arms on the other side of the flask. The hub was turned, too, as that gave a better guide to go by, and the joint was made the same as the other side. The cope was put back and rammed up, lifted off and finished. I would state in connection with this that if a molder is making a job where there is a vacant space outside the bar, before the flask is lifted off it is a good idea to take the trowel and cut square down along the bar on the outside. Then if other things are right he will get a clean fit. —T. W. in Browning's Magazine.

Practical Questions and Answers

Bearing Metals.

Ques.—What are the chief constituents of bearing metals and wherein are they more suitable for bearing surfaces than other metals?

Ans.—The chief essentials of a bearing metal are:

1. That it be strong enough to carry the load without distortion.
2. That its coefficient of friction with the metal which bears on it be small.
3. That it be easily molded or formed into the required shape.
4. That the bearing metal be soft enough so that any wear that takes place will be on the bearing metal and not on the journal.

The numerous alloys used as bearing metals have properties which fit, to a greater or less degree, these conditions. When backed by a casting they are strong enough for ordinary loads, some of course, being more suitable for heavy work than others.

The numerous experiments that have been conducted by bearing-metal manufacturers have resulted in very frictionless metals, although the coefficient of friction between two surfaces depends far more upon the efficiency of the lubrication than upon the composition of the bearing metal. The best systems of lubrication provide that a thin film of the lubricant completely separate two bearing surfaces.

The last two conditions are, of course, fulfilled by bearing-metal alloys.

There are practically as many different alloy compositions as there are brands of bearing metals on the market, some of them being very much alike while others are widely different. The chief constituents of bearing-metal alloys are, however, copper, tin, lead, zinc, antimony and iron. There are very few bearing-metal alloys which do not contain copper, and it forms the largest per cent. composition by far in most of them.

White metal is one of those containing no copper. Lead is contained in nearly all, forming a very large percent composition in some and small in others. Most of the metals also contain tin, mostly in small quantities, although there is one metal made up of 98 per cent. tin. Antimony is contained in many, but there are only traces of iron in any of them.

Copper Tubing by Electroytic Process.

Ques.—What is the electrolytic process of making copper tubing?

Ans.—The process is as follows:

A wooden core is turned up the size of the core of the pipe. This wooden core is coated with plumbago to form a conducting surface. In a bath of copper sulphate, acidulated with sulphuric acid, this is made the cathode, while a mass of partially refined copper is made the anode. A current of electricity being passed through the solution copper is transported from the copper cathode to the core of wood forming the anode. To ensure that the copper will be deposited evenly over the surface the wooden core is rotated in trunnions through which electrical connections are made, and a carriage, similar to a lathe carriage, on which is mounted a tool tipped with agate, traverses the length of the core, the tool pressing the copper down as it is deposited, the carriage being automatically reversed at each end.

The proper current density (about 10 amperes per square foot) being used the foreign metals in the copper anode fall to the bottom of the tank and can afterwards be recovered.

This process is the Elmore process. It is a successful process, practically, although there have been some commercial failures, but according to some authorities these failures were due to improper financing. The advantage of it over the drawn copper tubing method is that almost pure copper seamless tubing can be made, while it is practically impossible to draw copper tubing without causing oxidization, thus decreasing the strength. One of the practical disadvantages of the Elmore process is the difficulty met with in getting bends in the tubes.

What Determines Temper?

Ques.—What is it in the steel that determines its temper?

Ans.—The temper of a piece of steel is determined by the amount of carbon it contains. The higher the per cent. of carbon the higher is the temper. When steel is used for such tools as cold chisels, drifts, etc., the usual amount of carbon is one per cent. The amount of carbon in lathe tools, milling cutters, taps, drills, reamers, etc., varies from one to one-and-one-half per cent. according to the temper, which of a necessity varies according to the hardness of the work.

Machine Shop Costs

By G. C. Keith.

Paying System.

ON pay day, which should be a few days after the pay time ends to allow the time-keeper to make up his pay roll and the cashier to get the money counted and put in the envelopes, the men line up according to their numbers, presenting receipts for their pay and receiving their envelopes. This receipt is made out by one of the clerks, from the pay roll. They are distributed to the men before the hour of payment. The following is a good form of receipt :

"Note.—If this amount is not correct notify your foreman immediately. You must present this receipt or you will not be paid."

Another system of paying which is

$\$$ ..... CHECK No. .....

Received from ENGINE COMPANY LTD. the above sum for the half month ending.....

Date..... Full Name.....

NOTE,——

convenient, but not so commendable, is to carry around the envelopes, giving each man his pay on presentation of his receipt.

Rates of Employes.

To arrange the rates so that no time will be lost copying them into the shop statement and labor slips is an easy matter. Plain white cards 2 in. x 3 in. are arranged according to numbers in a small box. Thus :

101 21½

M. Rennie

It is then easy for a clerk to go through the box and write out the rates on his pay roll and other lists. When the time-keeper gets an order from a foreman for an increase the rate may easily be changed without destroying the card.

Employe's Record.

In every cost office should be found a record of all the employes, past and present. Two files should be kept and the time-keeper should keep the cost clerk informed of any changes, such as new men arriving and old employes leaving, increases, etc. If a man leaves the works the reasons should be at once written on his card, which should

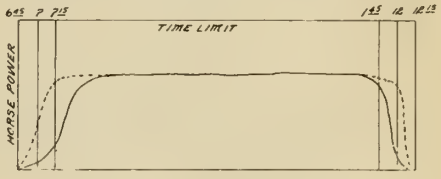
Fixing Prices or Time Limit.

To find the price or time-limit for a certain pattern several things must be taken into consideration—the setting up of the piece of machinery, handling, changing to perform a different operation, etc. Suppose we wish to arrive at the time-limit for shaping the base of a small engine 18 in. x 30 in. The long edge is placed at right angles to the tool. Two cuts are taken, a rough and a finishing cut. By timing we find that the shaper takes 15 strokes per minute, and by measurement with a rule it feeds 1-16 in. per stroke. The total width being 30 in., 480 strokes are necessary and take 32 minutes. A finishing cut will take 32 minutes more, making in all 64 minutes actual time. In ordinary work 20 to 25 per cent. is allowed for setting up, sharpening tools and margins, but this percentage varies with the nature of the work. The time allowed, therefore, would be an hour and ten minutes, but it will be found convenient to make a rule to take the nearest quarter hour. The time-limit will then be one and one-quarter hour. Supposing a man to be earning 14c. per hour on the shaper, the price for him would be 17c. each.

A Mechanical Check.

Probably one drawback to the premium or time-limit system is that some time a point is reached where the workman is afraid to produce more in fear of being "cut." Even in the case where a man is supposed to watch premium workers it is impossible to find out who is being paid too much for his work. Men have been known to dull their drills to keep from doing too much work. The only way to detect this is by an ordinary engine test, which must be carried on every quarter hour from seven to eight, eleven to twelve, one to two and five to six. From eight to eleven the horse-power used will be found to be about equal throughout. If the men are doing their work the horse-power used by the engine will be constant.

If the men are doing their work we get the dotted line. One factory dis-



covered their loss in this manner and the result was a cut in their piece-work prices. The output was increased 11 per cent. and the men still make as much as before, but they work a full day for it.

A lesson from the diagram which we should learn is to have the employes at the works on time and start their work on time. Men coming in late, men starting their work late, absentees and men leaving before the engine stops running means loss of power, a leak in the profits which should be stopped at once.

Electric Smelting Assured

WHEN Dr. Haanel, Dominion Superintendent of Mines, who has been investigating the problem of electric smelting at Sault Ste Marie for the Dominion Government, gave his first public detailed announcement as to the complete success of the method at the Canadian Club, Toronto, on March 12, he made a statement that will have a powerful influence on the future of Canada, practically assuring its commercial independence of all other countries. He said it was now proven that the vast deposits of iron ore in Canada, hitherto considered valueless because of their high sulphur contents, may be profitably utilized by the use of the water power with which Ontario and Quebec are so richly blessed, this meaning that Canada can undertake for itself the steel and iron industry, the basic industry of modern civilization, without having to import coal or ore for that purpose. Using entirely Canadian products, Canadian manufacturers will be able to make the tools and agricultural implements for the settlers pouring into the country, will be able to build the bridges and boats and railways which are to open up our vast territories, and make the machinery to be used in thousands of busy factories.

RETURNED MAR 19 1906

Commerce Founded on Iron and Steel.

"The iron and steel industries," Dr. Haanel said, "are the foundation of our modern civilization. To realize our dependence upon them, try to imagine what the state of affairs would be if our iron and steel industries were swept away. Transportation by railway and by boat as we have it to-day would cease, the machinery in our factories would be banished, and the comforts and luxuries of our life destroyed. We might better do without gold or silver than this much cheaper metal."

The commercial status of a nation, he continued, depended largely upon the development of the iron and steel industries. Not speaking of England, which was the pioneer in this work, Germany and the United States to a great extent owed their prestige to the development of their iron and steel industries.

The country which required to import its iron ore was handicapped in the race for commercial supremacy. In the fiscal year of 1903 and 1904 Canada had imported pig iron to the value of $43,000,000. Thus was Canada dependent on other nations for a material necessary in every industry.

In Canada, which was the Eldorado attracting a teeming population, the need for iron was increasing to provide tools and agricultural implements for the new settlers, structural material for railways, boats and bridges, and material for the modification of established and the inauguration of industries. To stimulate and encourage production of iron and steel from abundant raw material the Government had given generous bounties and imposed import duties.

The distribution of the raw material in Canada was peculiar. While the necessary coking coals for blast furnaces were found at the extreme east and west in Ontario, Quebec, Saskatchewan and Alberta were large ore deposits, but not coal deposits capable of furnishing coke for metallurgical purposes. If these deposits were to be used by processes of production at present in use, coke would

Dr. Haanel,
Dominion Superintendent of Mines.

have to be brought to blast furnaces erected in the vicinity of the mine or the ore transported to blast furnaces near the basis of the coke supply. The heavy transportation costs made the process uneconomical.

Deeply impressed with the disability under which the country rested in regard to the upbuilding of a steel industry, on entering his present position Dr. Haanel set himself to finding some other method or some other source of energy than the combustion of carbon in blast furnaces. Unless a new method could be proven to be practicable, immense ore deposits must remain undeveloped and regions remain waste which might otherwise teem with a vast industrial population.

The Electric Process.

The electric process had been profitably employed in different parts of Europe, especially in France. In the solution of the problem of applying electric energy to the extraction of metals from their ores, Captain Slassani in Italy and Herault and Keller in France had rendered conspicuous service. It was seen that if by the electric process pig iron could be economically produced, such countries as Brazil, Chili, Sweden, Norway, Finland, and Canada, all rich in iron ore deposits and possessing extensive water power, but lacking coal, would be able to render themselves independent of outside sources by employing the electro-themic process of manufactures of their iron and steel. From examination of processes in Europe, Mr. Harbord, the metallurgist of the commission appointed to investigate the matter by Hon. Mr. Fielding, decided as the probable output of 1,000 electric horse days 7.82 tons.

For the successful introduction of electric smelting of Canadian ores the following points which could not be settled by the European experiments required demonstration :

Could magnetite, which is our chief ore and which to some extent is a conductor of electricity, be successfully smelted ?

Could iron ores with considerable sulphur contents be made into pig iron of marketable composition ?

Could charcoal, which can be made from mill refuse and other available sources of wood useless for other purposes, be substituted for coke, which must be imported ?

And, lastly, what was the exact amount of electric energy required per ton of pig iron produced ?

Various Iron Ores Smelted.

To properly investigate these problems a sum was set aside by the Government and the work undertaken by Dr. Heroult of La Praz, France.

The Lake Superior Power Company of Sault Ste. Marie offered a building in which to erect the plant, and the use of one of their alternators of 300 electric horse-power capacity, free of expense for four months. The offer was accepted.

The experimentation on Canadian ores began in earnest the middle of February, the furnace being in operation night and day, with some intermissions, until March 5. During that time about 150 casts were made, yielding about 55 tons of pig iron. For the first experiments the ores employed were hematite, such as used by the Algoma Steel Company in their blast furnaces ; for the remainder of the experiments different classes of Canadian magnetite from the different sources of supply, all of high sulphur

content, with the exception of the Wilbur magnetite, which was low in sulphur, were employed.

The Furnace Described.

Dr. Haanel used a tumbler to describe the furnace. In it the ore was placed and into the midst of it a large electrode inserted. The electric current came from this electrode and through the metal to the bottom of the furnace, where it was carried off by another wire. The heat caused by the resistance offered to the current by the metal produces the heat which completes the smelting process.

Even the first experiments with magnetite showed that our fears had been groundless and that magnetite could be smelted with as much facility as hematite and with an output equal to that of the best experiment made with hematite.

"Moreover, since it was important to substitute, if possible, charcoal, which can be cheaply produced in Canada, for coke, which is dear, must be imported, the changes were made with charcoal. No difficulty was experienced whatsoever, the furnace working quietly and regularly, requiring little attention to the regulation of the electrodes.

"Analysis of the iron produced soon proved that, although the slag was not particularly basic, the sulphur could be caused to pass into the slag, resulting in a pig iron containing a few thousandths of one per cent. of sulphur.

Output Greater Than Expected.

"In every instance the output was far greater, in several instances one-third greater, than the figures adopted by Mr. Harbord, in the report of the Commission on Electric Smelting."

Experiments with roasted and briquetted nickeliferous pyrrhotite, containing 1.6 per cent. of sulphur, were equally successful, furnishing a ferro-nickel iron pig containing 4½ per cent. of nickel, and virtually free from sulphur. The estimated value of this product was $40 to $44 a ton. So successful have these experiments proven that the Lake Superior Power Corporation have decided to acquire the Government plant for the purpose of converting their stock of briquetted ore into marketable, ferro-nickel pig.

One of the most important points in the investigation, which could not be successfully settled by the experiments at Livet, was the consumption of the electrodes, and it was found that the consumption was beyond expectation small, and that an electrode which had been in use for three weeks, and during that time had been exposed to free air in an incandescent state for many hours, and had been used for melting down charges, which is always attended by waste of electrode without corresponding output in metal, that even with this severe test the consumption per ton of pig iron produced was between 15 and 20 pounds. According to Mr. Herault's estimates, this means an outlay of 30 cents per ton of pig iron.

Poor Ore Made Valuable.

"Many of our magnetites are too high in sulphur to be handled by the blast furnaces, and consequently have so far been of no commercial value. But the very best of pig iron, as has been proven, can be made from ores which contain as high as one per cent. of sulphur. A blast furnace will not usually handle an ore which contains one-tenth of one per cent. of sulphur and requires therefore an ore which cannot be got at a low figure. The Algoma Steel Works pay, I understand, $4.50 for the hematite ore which they use in their blast furnaces. A pig iron equal in value and lower in sulphur content can be made by the electric process from sulphurous ores which could be bought for $1.25.

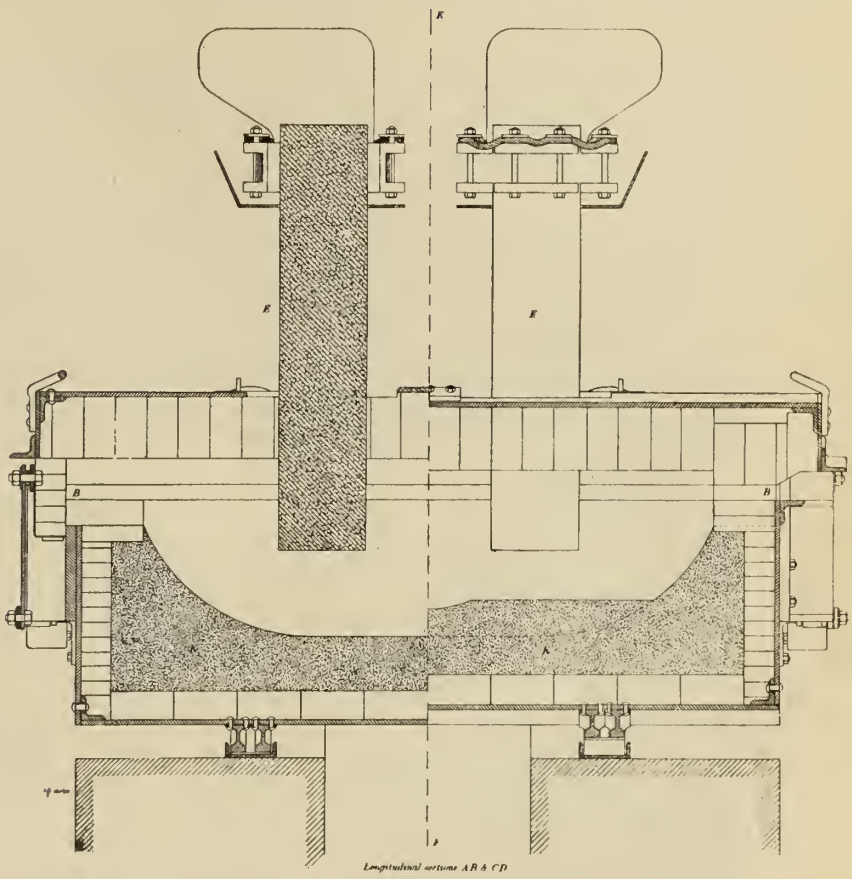
"Regarding water power required for the application of this process, it may be stated that many water powers exist in Ontario surrounded by iron ore fields in localities ill adapted for the application of electric energy for any other purpose, and could be developed to furnish an electric horse-power a year from $4.50 to $6.

"With such a price for the energy required, the small consumption of electrode, the cheapness of ore employed, and the peculiar excellence of the pig iron produced, electric smelting of iron ores in Canada, using charcoal or peat coke, made from our peat bogs of enormous extent, may be pronounced a commercial success. Under the prevailing conditions in Canada it now only remains for the engineer to design a plant on a commercial scale, say of 100 to 150 tons daily output, with all the necessary labor-saving appliances.

Blast Furnace Outclassed.

"Just as in the case of the blast furnaces, so likewise with the electric furnace, experience gained will result in further economy, and the day may not be far distant when the carbon monoxide, which is of high calorific value, and which at present, as a product of the reaction taking place in the electric furnace, is allowed to escape without utilization, will be employed for increasing the output by at least a third or half. If that should take place the blast furnace could not compete with the electric furnace even under the conditions where coke might be cheaper than at present quoted in Ontario and Quebec.

"A further advantage of the electric process is that the units employed are comparatively small and cheap of construction. A unit of 1,500 h.p. is perhaps the largest that under present circumstances should be constructed. Such



Cross Section of Heroult's Furnace, front view

a unit would have an output of about 18 tons per day and corresponds in size to about the larger Swedish charcoal blast furnace. With the present advance which has been made in the transference of electric energy, batteries of electric furnaces could be set up at various iron ore deposits which could be fed with electric energy from some centrally located water power, thus affecting a saving of the transportation costs of the ore from the mine to the furnace.

"When a deposit is worked out the furnaces may be moved to the next deposit, simply lengthening the wires which carry the high tension current to the transformer of the plant."

The utilization of ores of high sulphur content which cannot be used in blast furnaces is of especial importance, because the question has arisen, how long the present supply of blast furnace iron ores is likely to last, and when these ores are exhausted and none but sulphurous ores and titaniferous ores are available, the stacks of numerous blast furnaces will be silent and smokeless, having been supplanted by the electric furnace, which can successfully heat an ore which blast furnaces cannot handle.

Results of Experiments.

The following is a summary of the results of the experiments which have been completed under Government auspices at Sault Ste. Marie:

1. Canadian ores chiefly magnetite can be economically smelted by the electro-thermic process.

2. Ores of high sulphur content can be made into pig iron containing only a few thousandths of sulphur.

3. The silicon content can be varied as required for the class of pig to be produced.

4. Charcoal which can be cheaply produced from mill refuse or wood, which could not otherwise be utilized, and peat coke made from peat, of which there are abundant deposits in Ontario and Quebec, can be substituted for coke without being briquetted with the ore.

5. A ferro-nickel pig can be produced practically free from sulphur and of fine quality from roasted nickel ferrors pyroholite.

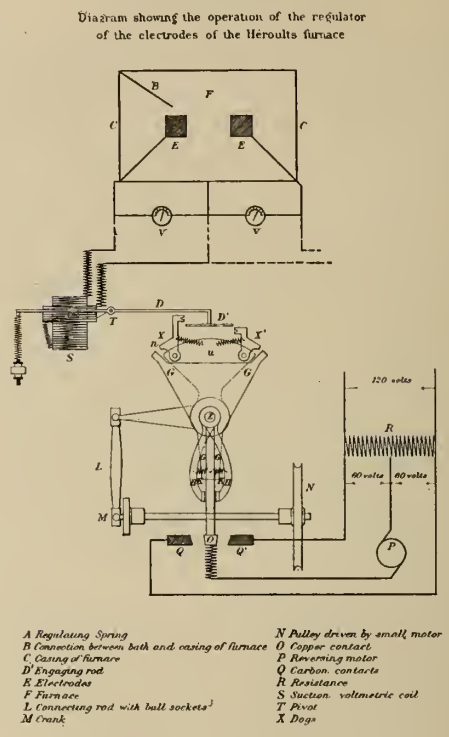
6. Pyrite cinders, resulting from the roasting of pyrite in the manufacture of sulphuric acid, and which at present constitute a waste product, can be smelted into pig iron by the electric process.

7. Titaniferous iron ores containing up to 5 per cent. can be successfully heated by the electro-thermic process.

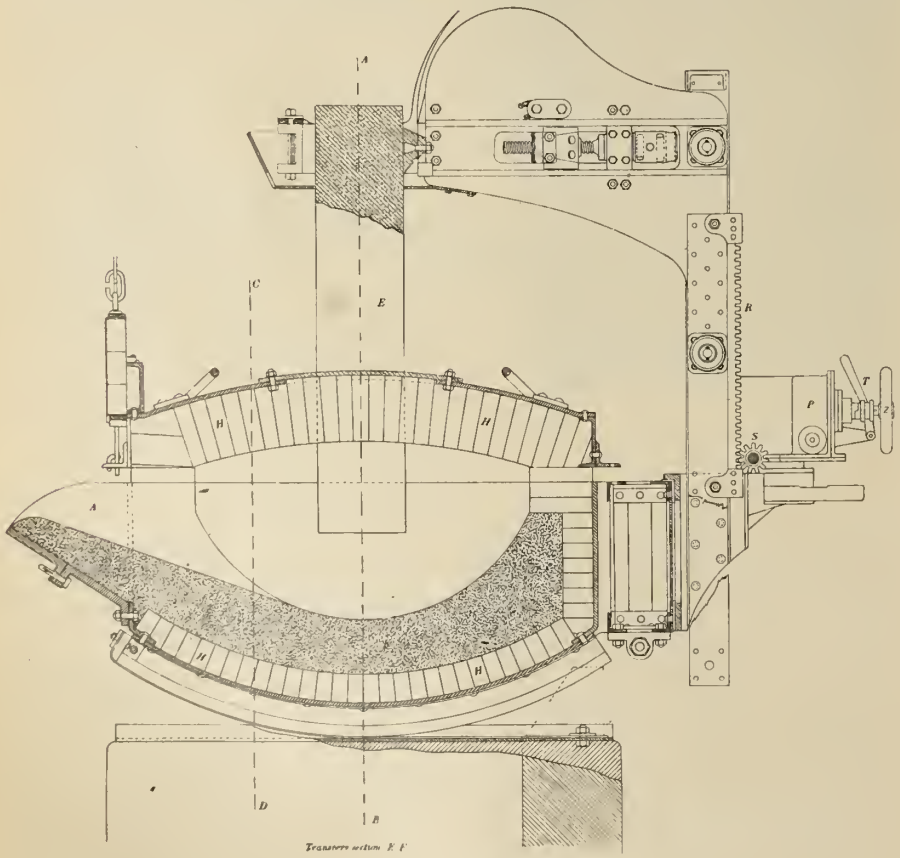
The result of the introduction of electric smelting into Canada may be summarized as follows:

(1) The utilization of our extensive water power, which cannot at present be profitably employed for any other purpose.

(2) The utilization of the large number of iron ore deposits, which, on account of their high sulphur content, cannot be treated by a blast furnace, and have so far been valueless.



Method of Operating Heroult's Furnace.



Cross Section of Heroult's Furnace, side view

(3) The utilization of our extensive peat bogs for the production of peat coke to be used as reducing material for the operation of electric furnaces, and the utilization of mill refuse and sawdust, for which there has been so far no practical use.

(4) Rendering Canada independent of fuel import for metallurgical processes.

(5) Enabling Canada to produce her own pig iron from her abundant sources for home consumption, and consequently retaining in our own country the money which otherwise would have to be sent abroad to purchase pig iron in the crude and manufactured state.

(6) The development of steel plants and rolling mills using only electric energy.

Associated with Dr. Haanel in his work was Dr. Heroult, one of the leading electro metallurgists of the continent, whose system was adopted in carrying out the experiments. Some details of the Heroult furnace, as operated in France, and its method of regulation, are given.

Heroult Process.

The furnace is of the tilting pattern. It consists of an iron casing lined with dolomite brick (HH) and magnesite brick around the openings. The hearth is formed of crushed dolomite (K) rammed on top of the dolomite brick lining of the bottom of the iron casing. Two electrodes (EE) pass through the roof of the furnace, which, in the Kort-

fors furnace were water jacketed for a short distance above and below their passage through the iron casing of the roof. The current passes from one electrode through the narrow air gap left between the electrodes and the slag line, into and through the slag to the molten metal, along it, through the slag and second air gap, to the other electrode. An alternating current of 4,000 amperes and 110 volts was delivered to the electrodes. The intensity of the current passing through the bath is regulated by adjusting the width of the air gap between the electrodes and the slag line. This adjustment is effected either by hand or automatically by a specially constructed regulator. In the former case the motor (P) is thrown out of action by lever (T). (Z,) operating on pinion (S,) which engages the teeth of rod (R,) is rotated right and left handed to lower or raise the electrodes. Diagram (Fig. 3) illustrates the principle of the action of the automatic regulator.

In Fig. 3 (B) is an iron wire connecting the bath of metal with the iron casing (C) of the furnace. The current due to the difference of potential between the metallic bath and the electrode (E) passes through the voltmetric suction coil (S,) the movable outer coil of which operating the rod (D) pivoted at (T,) and regulated by spring (A,) imparts motion to the horizontal staff (D) in a vertical plane, with every variation of difference of potential in the circuit. (N,) a pulley driven by a small motor, operating by means of the crank (M) and the connecting rod (L,) oscillates the part (U,) which is pivoted at (Z). The dogs (XX) attached to (U) partake of the oscillation of (U,) but in their backward and forward motion fail to clutch the staff (D) as long as the variation of voltage in the circuit does not exceed 2 volts ; when this limit is exceeded either way (D) rises sufficiently high, or is depressed sufficiently low, to be clutched by either (X) or (X'). When this occurs the projection of the respective dog is brought into contact with the respective side of the triangular plate (GG,) to which the prongs (HH,) pivoted at (Z,) are attached by springs (KK). This results in bringing the copper piece (O,) the suspending rod of which is also pivoted at (Z,) into contact with the respective carbon block (Q.) From the diagram it will be seen that the direction of the rotation of the motor (P,) which raises or lowers the electrodes (EE,) depends upon the contact made by (O) with either (Q) or (Q',) and hence upon the rise or fall of the voltage in the circuit beyond the limit of 2 volts.

"Not how much, but how often, is the way to handle your advertising proposition."

LES CHATS FALLS.

LES CHATS FALLS, of which an illustration is given, is one of the many promising water power possibilities of the Ottawa River, and offers one of the best hydraulic development propositions available. It was stated very recently by an expert that electrical energy could be exploited here and delivered to the bus-bars at a cost of from $4.50 to $6. The significance of this is realized when it is remembered that in some cities in Canada manufacturers are paying anywhere from $40 to $70 a horse-power per year for electrical energy, and that it costs from $30 to $40 a horse-power per year to develop power by steam in small units.

Les Chats Falls—On the Ottawa

This picturesque fall is situated thirty-three miles from the city of Ottawa, and here the total volume of the Ottawa River passes, dropping about sixty-five feet, and offering for the use of man thousands and thousands of horse power of available energy. In this neighborhood there are large quanties of iron ore. Now that the connecting link between a water power and the reduction of iron through the agency of electricity seems assured several Pittsburgs should arise in Northern Ontario, the centres of enormous wealth with none of the smoke and soot and grimy disadvantages that have heretofore been characteristic of large industrial centres.

Steam Gas Electricity Compressed Air Water

SMART-TURNER CENTRIFUGAL PUMP.

THE accompanying cut illustrates a side suction centrifugal pump as built by the Smart-Turner Machine Co., Limited, Hamilton, Ont. It is designed so that by loosening a few bolts the pump shell may be revolved on the hood of the frame, which enables the discharge to be taken off at any desired angle. The runner or piston of the pump is of the hollow arm pattern, which is the design on which the frame of the Heald & Sisco pump is mainly based. The construction is such that there are no dead spaces and the water is not thrashed by the arms, but is forced steadily toward the discharge.

It will stand very much more wear than the ordinary arm piston without allowing the water to slip back into the suction. These pumps are also designed for direct connection either to gasoline engines or electric motors.

Smart-Turner Centrifugal Pump.

A PRACTICAL ELECTRIC HOIST.

THE illustration shows a two-ton Yale & Towne electrical hoist, which consists of a motor, controller and hoisting gear balanced on a single top hook, so that the centre of gravity does not change with or without load. The suspension is all taken on the hooks and two steel frame plates, so that no cast iron is in tension. The top and bottom hooks swivel, and are equipped with ball bearings. The single top hook also admits of a flexible connection between hoist and trolley or other overhead support, to prevent side strains when the hoist is lifting out of a true vertical line. This top hook facilitates using the hoist on short erecting jobs, or enables it to be attached permanently to an eye-bolt or overhead trolley. Installation involves simply hanging the hoist and connecting two wires.

All machines are thoroughly tested for defects in material and workmanship before leaving the factory. The insulation must stand a breakdown test of 2,200 volts, alternating from a transformer of adequate size. All parts are made to gauge, thus securing complete interchangeability. The gearing, motor, controller, and other vital parts are easily accessible, facilitating adjustment or renewal of parts without completely dismantling the hoist, or requiring it to be sent back to the factory. The rugged simplicity of the hoist enables its use in the hands of inexperienced workmen. No skilled electrician or operator is required.

The hoist is regularly built in 1, 2, 4 and 6-ton sizes; others to order. The height of lift is governed by the winding capacity of the drums, and is 45 feet as a maximum for the 2-ton size.

The efficiency has been developed to a very high point. The cost for lifting per foot ton is $.000303, figuring the cost of current at 10c. per kilowatt hour. On this basis one cent's worth of current will lift a 1-ton load 5 feet high six times, or a total of 30 feet; ten cents' worth of current will lift a 1-ton load 5 feet high 60 times, which is equal to lifting a ton 300 feet. The economy of such equipment is self-evident.

One firm in Nova Scotia reports, after using one each 2 and 4-ton hoists constantly for one year, that "They have not cost one cent for repairs and show no signs of wear." Thus it is achieving a reputation for resisting wear like that enjoyed by the Yale & Towne chain blocks. The hoist is having a wide application both in this country and the United States.

A Practical Electric Hoist.

The following plants show the variety of work to which it has been adopted: Machine shops, structural shops, locomotive works, foundries, bridge works, smelting and refining works, street railway shops, railroad repair shops, ship yards, United States navy yards, car works, iron and steel works, sheet and tube works, boiler shops, power plants, electric light plants, building and construction, warehouses, erecting shops, etc. The Canadian Fairbanks Company, Limited, Montreal, Canadian sales agents for the Yale & Towne Co., will be pleased to give any further particulars desired.

THE IMPROVED FRICTION COUNTERSHAFT.

ACCOMPANYING engravings show a new friction countershaft which is quite an improvement over now existing forms.

It is noted particularly in respect to driving power, ease of operation, noiselessness, and in giving the workman perfect control of his machine. Its driving power will be understood when it is pointed out that the friction shoes are screwed into contact with the rim, a tight engagement being thus obtained with a very small effort at the shifter lever. The force required to engage this clutch is so small that with the tip of the finger at the shifter handle, the friction is set tight enough to slip the belts. It will be noticed that the friction gradually engages and that the operator can apply any desired amount of driving power to his machine. The extent to which this feature can be utilized is shown by the fact that a piece of work may be put on the lathe centres and cut in two with a parting tool without danger of breaking the tool, because the friction can be set just tight enough to drive the cut and to slip when the piece comes apart and pinches the tool. There are many other occasions on which this feature is useful, as in bottom tapping, or at any time when tool or work can be protected against breakage by the slipping of the friction. This same property makes it easily possible to slack down the speed for measuring or examining the surface of the work when stopping would leave a mark on the work. When used over a lathe it can be used as a brake to quickly stop the machine by lightly engaging the "backing" friction before bringing the handle to the "off" position. The makers have spared no pains to make this countershaft very good all around. Instead of the old two-point suspensions the self-oiling boxes are so supported as to be free to swing in all directions and will not bind the shaft if the hangers are not put up squarely. No tools are required to adjust the friction, and belts are not thrown off for this. The pulleys run on sleeves set-screwed to the shaft, providing a large bearing surface and containing the oil holes, so that the belts need not be thrown off for oiling. The drip-cups are taken off by withdrawing a cotter pin, doing away with all spilling of oil, as with those that have to be screwed out when full. Taking everything in consideration this countershaft ought to add materially to the output of the machine it is used over. It is made by the Wilmarth & Morman Company, Grand Rapids, Mich.

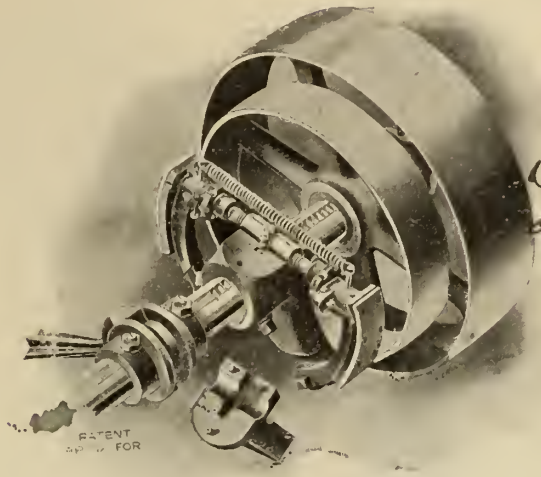

Fig. 1 Improv d Friction Countershaft.

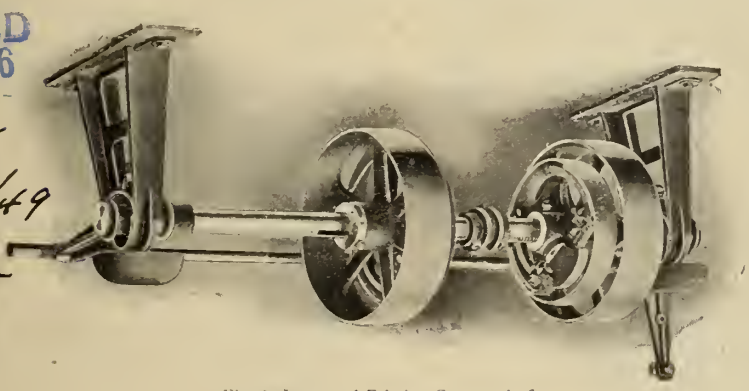

Fig. 2 Improved Friction Countershaft

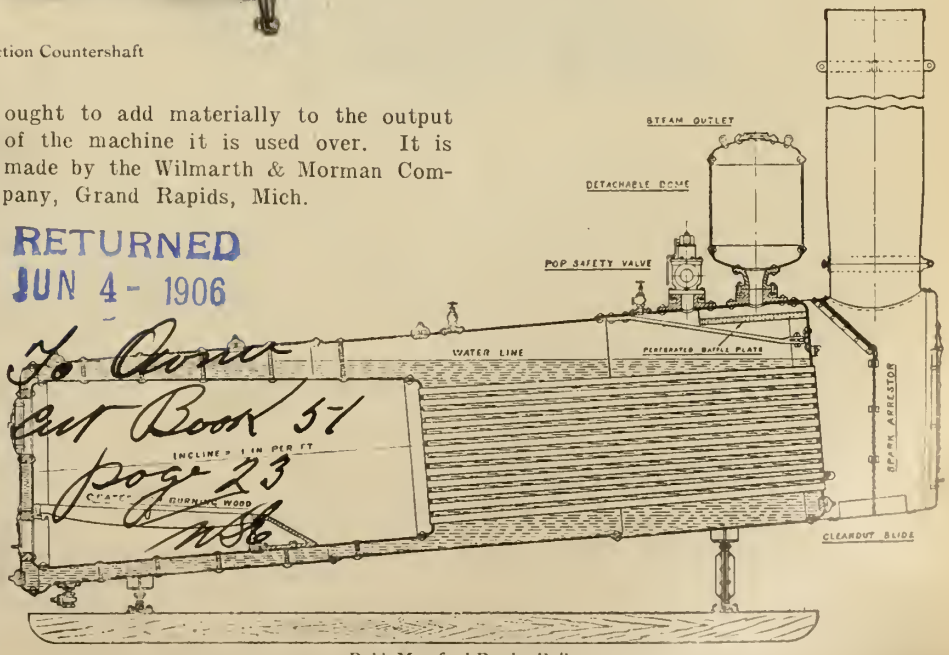
ROBB-MUMFORD-BRADY BOILER.

IN the Maritime Provinces there has been a great demand for a suitable portable boiler for saw mills, and to meet this demand, the Robb Engineering Co. have recently designed a boiler known as the Robb-Mumford-Brady portable boiler, which is illustrated herewith.

This boiler, as will be seen from the accompanying cut, consists of a cylindrical shell, with an inclination from the horizontal of about one inch to the foot, having in it a cylindrical fire box. The fire box is tapered, making it parallel with the shell on the bottom, allowing ample space between the fire box and the shell for water, while the top is parallel with the water line. The tubes ex-



Robb-Mumford-Brady Boiler.

tend from the back end of the fire box to the back end of the shell, running parallel as in a locomotive boiler. This permits the water line of the boiler to amply cover both the fire box and the tubes and furnishes a large disengaging surface for the steam to rise from the water without foaming. In a marked degree this boiler combines safety, durability, simplicity, capacity, portability and economy, coupled with quick steaming power, good circulation, and low first cost.

The boiler is constructed with a water front, instead of a casting, so that there is no cast iron exposed to the fire, and is provided with three hand-holes in front at the top, in line with the top of the fire box, which permit the use of a scraper for cleaning the entire top and sides of the fire box. A hand-hole is also placed in the front head below the fire box, in the rear below the tubes, and on top of the shell in line with the tube sheet for full examination and cleaning purposes. The rings forming the fire door and ash door openings are of forged steel, and the doors are made of heavy steel plate fitted with baffle plate. The lower portion of the shell at front end, near blow-off, is flanged slightly, thus forming a pocket for the deposit of any sediment and for the admission of a hand-hole. The rear end of the fire box is flanged on the sides, making the tube sheet oval in shape, thus bringing the tubes parallel with the sides of the shell, as shown, and in vertical rows. The fire box is cylindrical, the tube sheet only being oval.

The boiler is provided with a detachable dome, having the heads dished equal to the radius of the diameter, and is attached to the shell by means of steel nozzles, the nozzle on shell having slotted holes. All nozzles for safety valve and other fittings are cast steel rivetted to shell for flanged fittings. A dry pipe is also provided with perforated or slotted holes on top, having an area equal to seven times the steam outlet. The smoke box is made of 3-16 inch steel plate, attached to the boiler by slotted studs and steel keys, and being detachable, can be removed readily for handling. The rear end of the smoke box and tube cleaning door are made of heavy steel plate, the door being fitted with a baffle plate, and provided with an attachment to support the door in position for cleaning tubes. When necessary, or when wood is used for fuel, a detachable spark arrestor is provided in smoke box. This spark arrestor is made of heavy steel wire netting and is so arranged that it can be removed instantly for cleaning the tubes, and being in a vertical position, sparks will not adhere to it. The spark arrestor is of ample area so that it will not affect the draft, and a sliding clean-out door is provided in the bottom of the smoke box.

The boiler is supported on two saddles of steel and angle iron construction, being light and strong and so fitted that they may be easily detached for rolling the boiler if desired.

No cast iron work whatever is used, except the grates and bearers, which can be made to suit wood or coal, and either plain or rocking pattern, as desired.

Pilkington Compressed Air Hammer.

PILKINGTON POWER HAMMERS.

IN a previous issue some reference was made to this new line being manufactured by Peter Pilkington, Limited, 75a Queen Victoria street, London, England, since when further particulars have been received and two illustrations are shown. The saving affected by the use of these compound compressed air hammers over steam is about two-thirds in fuel, rendering them powerful and economical. They are worked from an air compressor through the medium of high and low pressure receivers. The hammer has two cylinders, one above the other, the top one being the low pressure cylinder for lifting the head and the lower cylinder is used for making the blow by high pressure air. After a blow has been struck the same air is conducted into the low pressure cylinder and is again used for lifting. Light blows and lifting of the tup are always effected by low pressure air. It is claimed for these hammers that they will do anything a steam hammer will do, will strike dead blows, hold down and squeeze, and, if necessary, can be made to work self-acting, as well as by hand lever.

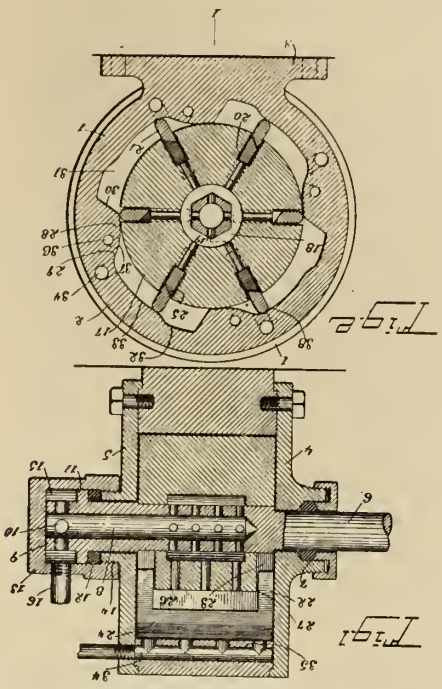
MORE ROTARY ENGINES.

A FEW months ago an account of the Canadian built rotary engine was given in these columns. Recently, two other rotary engines have been brought before the public. One of these was on exhibition in Madison Square Garden as being suitable for propelling automobiles, both for furnishing power and electric light plant. Among the advantages claimed for this engine are that the cost of construction will be about one-half less than the present machines. The economy of steam by this system of cut-off and expansion is, in every particular, equal to the Corliss

engine, and its speed can be varied from 50 to 3,500 revolutions a minute. It is reversible and its adaptation for all kinds of boats will fill a long-felt want, as it can be connected direct to the propeller shaft, and for generating electricity it will be adopted for the same reason.

Another, patented by Robt. C. McLean, of Cleveland, is shown in the accompanying illustration. Further interest is added to this from the fact that part of it was built at the Canada Machinery Co's plant at Point Edward, where the inventor was employed for some time. This engine takes steam 24 times per revolution as positive piston motion, steam expansion, and no back pressure. Steam is admitted into directly opposite expansion chambers simultaneously, while two other pistons are working under expansion, thus four pistons are always at work, so placed as to make the engine practically frictionless.

The operation of this engine is as follows, it being understood that the direction of rotation is to the right, that is, with the hands of a clock. The presence of steam in the steam space 26, forces the pistons or valves 21 outwardly, maintaining their rounded noses 38 against the wall of the casing. In the position in which the drum 17 is shown



New Rotary Engine.

25 of the pistons are disposed beyond the periphery of the drum 17, so that the steam behind the valves is allowed to escape. This steam filling the expansion chambers behind the pistons, of course, operates to rotate the drum and advance the pistons in the direction of the elevated faces 33 and toward the inclined faces 29. When the rotation has continued sufficiently, the exhaust-ports 34 are uncovered at their branches 35, so that the steam escapes, creating an exhaust from the expansion chamber. The steam which remains in the chambers in front of the pistons when they have passed beyond the exhaust ports 34 is expelled through the auxiliary ports 36. In this way no back pressure is developed at the abutments 28 which might tend to prevent the rotation of the engine. When the pistons pass the most elevated points of the abutments 28, they slide down or outwardly on the inclined faces 30 toward the faces 32, admitting steam again to the expansion chambers. This admission of the steam continues, of course, until cut-off occurs by the inward movement of the pistons, when they pass up to the elevated faces 33.

cut-off has just taken place. This cut-off occurs when the ends of the pistons 21 ride up from the surfaces 32 upon the elevated surfaces 33. When the pistons have their noses resting against the depressed faces 32, the inner edges

IMPROVED BOILER-TUBE CLEANER

A NEW boiler-tube cleaner having many points of interest is manufactured in Pittsburg. The most interesting feature of the tool is in the fact that its moving part is driven by a miniature water turbine. The body of the turbine is made in one casting, and within the casing is a spider which forms a bearing box containing a journal

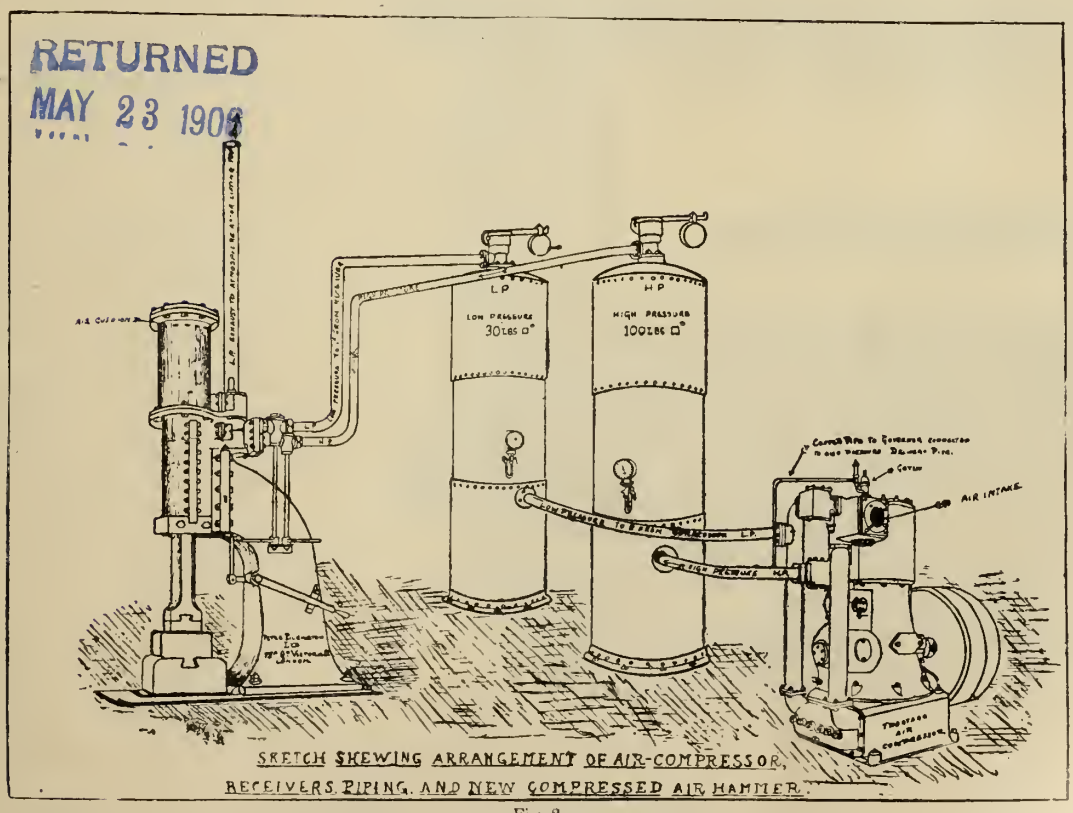


Fig. 2.

for the shaft. An oiling chamber, closed at one end, is in one arm of the spider and in the other is a ball valve through which the bearing is supplied with oil. The revolving part or turbine wheel is screwed into the rear end of the shaft, so that its weight will have a tendency to balance the weight of the cutting tool on the other end of the shaft. The stationary nozzle part, which admits water to the veins, is back of the turbine wheel. On machines for straight tubes there is used either a special hose coupling or a coupling standard pipe thread. For use in bent tubes there is provided a universal coupling which is interposed between the shaft and the freely swinging arm head, by which arrangement the machine may be used equally well in either straight or curved tubes.

NEW GASOLINE MOTOR CAR.

THE accompanying cut shows a No. 16 gasoline motor car manufactured by Fairbanks, Morse & Co., Chicago, and is one of several different styles of cars of this class they are at present building.

Early in the Summer of last year Mr. Geo. H. Webb, chief engineer, Michigan Central Railroad, made an inspection trip over the system with one of these cars, and below is some data which is

Gasoline Motor Car.

of special interest, showing as it does what has been actually accomplished with the gasoline motor. The total distance traveled by the car was 4,347 miles and the total amount of gasoline used was 231 gallons, or an average of 19.7 miles per gallon of gasoline. The records show that on the run from Jackson to Allegan, a distance of 175 miles round trip, only 7½ gallons of gasoline were used, or 23.3 miles per gallon. The total cost per mile, including lubricating oil, battery cells and everything excepting wages of man in charge, was 9-10ths of a cent. Most any railroad man can figure out that this is quite a saving as compared with a steam locomotive pulling a private car. This gasoline car has its advantages also because of its ability to attain a high rate of speed and maintain it on a long run. From Marshall to Allegan, 66.4 miles distance was made in one hour and forty minutes, or at the rate of 40 miles per hour, and they report they never stopped the engine once. The distance from Tekonsha to Harris—29 miles—was made in 45 minutes, and the best run of the entire trip was made from South Haven to Kalamazoo, a distance of 39.6 miles in 45 minutes, or at the rate of 52.94 miles per hour.

THE KERR TURBINE IN CANADA.

The Kerr turbine will be manufactured in future in Canada by William Stephenson, 24 Bay street north, Hamilton, Ont. This shop has been established for some time, and the Kerr Turbine Co., of Wellsville, N.Y., are under contract with him for the manufacture of these turbines for all purposes for which they are applicable. The particular line will be for direct coupling to generators from 2 k.w. to 300, as well as for driving blowers, fans, centrifugal pumps, etc.

WESTINGHOUSE CHARGING RECEPTACLE.

THE extensive use of electrically operated vehicles and the varied application of storage batteries for train lighting, small electric locomotives, storage battery cars, etc., has created a demand for convenient and durable accessories, one of the most important being a charging receptacle that will withstand hard usage and can be handled without danger of short-circuiting the line when inserting or removing the plug.

Westinghouse Receptacle.

With this idea in mind the Westinghouse Electric and Mfg. Co. have developed and placed upon the market a charging receptacle that will meet the most rigid requirements.

It consists of a cast metal case, circular in form, that occupies a minimum amount of space. Within the case are suitably mounted contacts for receiving the plug. A hinged lid at one end, held normally closed by a coiled spring, affords access to the interior. The receptacle being entirely enclosed effectually protects it from dirt and water.

The plug and contacts within the receptacle are so designed that it is impossible to cause a short circuit when inserting or withdrawing the plug.

The receptacle may be provided with a swivel attachment, conforming to standard railway practice, which is a decided advantage as it admits the pulling out of the plug when the vehicle or car starts, the receptacle swinging in line with the cables, and allowing the plug to pull out without danger of breaking the cables or contacts.

The charging plug shown in the accompanying illustration is intended for use with the charging receptacle. It is furnished with or without cables, as desired. The construction is rugged and all parts are well made, insuring a long period of service.

ABOUT CATALOGUES

By mentioning Canadian Machinery to show that you are in the trade, a copy of any of these catalogues will be sent by the firm whose address is given.

Reece Screw Plate. A booklet designed to interest mechanics in connection with the Reece screw plate set of stocks, taps and dies. E. R. Reece Co., Greenfield, Mass. 3 1-2 x 6.

Jacks. Patent lever jacks, geared lever jacks, screw jacks and hydraulic jacks, are described in the 29th annual illustrated catalogue of the Joyce Gridland Co., Dayton, Ohio. 94 pages, 3 3-4 x 5 3-4.

Marine Gasoline Engines. The Hamilton Motor Works, Hamilton, Ont., are sending out a neat little booklet describing various types of gasoline engines and the motors for which they are used. Complete instructions regarding the operations of the engine are also given. 16 pages, 4 1-2 x 6.

Engineering Specialties. The 1906 catalogue of the Georgian Bay Engineering Works, Midland, Ont., besides giving illustrations and a description of the different hoisting engines manufactured by this firm, take up various special apparatus such as swinging drums for derricks, pile hammers. At the back of the catalogue useful information regarding steam and water is given. 16 pages, 6 x 9.

20th Century Machine Tools. The most complete catalogue yet issued by B. F. Barnes Co., Rockford, Ill., has just been received. It describes in some detail, with splendid illustrations, the different lines of upright drills, gang drills, lathes, tool grinders, key seaters, and special machinery manufactured by this firm. The new features incorporated in these machines are dealt with. 79 pages, 6 x 9.

Mechanical Draft. Bulletin No. 75, "What it is, what it does" has just been issued by B. F. Sturtevant Co., of Boston, Mass. This booklet not only briefly presents the salient features of this system of draft production, but illustrates a variety of plants which clearly show "what it is." The suggested query in the words "what it does" is answered thus: It does what an ordinary chimney is incapable of doing.

Gas and Gasoline Engines. The Toronto Gas & Gasoline Engine Co. have just issued a handsome catalogue describing the firm's line of manufacture. Illustrations are given of the different designs of engines made as well as the various types of motor boats. Views are also shown of plants where various sizes of these engines are installed. A number of testimonial letters are given, received from satisfied customers of the company. Size, 6 x 9.

Card Index Systems. A beautifully arranged catalogue, complete with high-class illustrations in colors, has been issued by the Office Specialty Mfg. Co., Wellington street, Toronto. This catalogue deals with the different systems devised by this firm and the many uses to which they are adapted. Forms used in these are shown as well as the ruling for the different devices. The catalogue is very complete and well arranged. 48 pages, 7 x 9.

Boilers. Robert Jenkins & Co., of Rotherham, England, have published their 1906 list of heating and range boilers, and make it the occasion to announce their jubilee year, the business having been established in 1856. The list is well printed on coated paper and contains illustrations of wrought iron boilers, (welded and rivetted), vertical boilers, hot water valves and hot water heating apparatus as manufactured by this firm. From cover to cover, there are 128 pages of matter.

Imperial Plug Driller. The latest catalogue issued by the Canadian Rand Drill Co., Montreal, Que., describes the different types of the Imperial plug driller, which is bound to have a decided effect on former recognized methods of rock excavating. Views of different operations are shown. 11 pages, 6 x 9. Another small catalogue is devoted to recent Rand productions illustrating various lines manufactured by this company. Size, 3 1-4 x 5 1-2.

The Siegwartbeam. The International Siegwartbeam Co., Lucerne, Switzerland, are sending out a very exhaustive catalogue describing the many various adaptations of the Siegwart hollow concrete beams. This catalogue is beautifully illustrated from beginning to end, describes various tests made on these beams and illustrates many buildings in which they are incorporated. All interested in cement or concrete structure work should have a copy of this catalogue. 117 pages, 6 x 9.

BOOK REVIEWS.

Shop Notes. The annual publication from Popular Mechanics, showing easy ways to do hard things. 414 pages, profusely illustrated. Price, 50 cents. Chicago: Popular Mechanics Co.

Everyone acquainted with Popular Mechanics knows the number of ideas in reference to shop kinks published each month in this interesting magazine. From beginning to end the book is full of descriptions of ingenious contrivances, most of them dealing with matters of every-day practical application. Here are to be found many suggestions for the mechanic, the handy housekeeper or the small boy, as well as information of no small value to the every-day reader.

The Honorable Peter White, by Ralph D. Williams, editor of the Marine Review. A history of the Lake Superior iron industry in the form of a biographical sketch. Cloth bound; 205 pages: illustrated. Cleveland: Penton Publishing Co.

To make a fascinating story of the Lake Superior iron industry, which is in itself one of the greatest industrial marvels in the world's history, the author has interwoven with it the life of one who was from the start a part of that industry, giving it a touch of romance and human interest that cannot but appeal to the readers of the volume. From the early days when the iron ore was drawn from the mine to the edge of the lake in sleighs in Winter time to be shipped down the lake, whence it had to be portaged past the Sault Rapids and then reshipped, to the present time when this iron trade has grown to be the greatest in the world, the reader is taken step by step and shown the various developments. Early in the history of this industry a thousand tons was a big pile to have ready when sleighing came to be drawn to the lake shore. Last year 30,000,000 tons or more were brought through the Sault Ste. Marie Canal from this source. In the early days methods were primitive, but to-day the speed and economy with which the ore is handled is a revelation to one not intimately acquainted with this field. The part Mr. White plays in this great enterprise is brought out, as well as the influence of other men on the industry. As a matter of mere interest and attractive reading the book is a fascinating one, so that anyone, whether particularly interested in the iron industry or not, could read this volume with pleasure and profit.

Machinery Development

Metal Working **Special Apparatus** **Wood Working**

A NEW HAND DRILLING MACHINE

A NEW hand drilling machine just brought out by A. B. Jardine & Co., Hespeler, Ont., embodying several important improvements is shown herewith. It is provided with the ordinary automatic feed for a post hand drilling machine, a lever and pawl taking reciprocating motion from an eccentric on the driving shaft, the pawl engaging with a ratchet wheel on the feed nut. The machine has an automatic quick return of feed. A clutch is feathered on the feed screw, and engages with a clutch on the drill spindle. When the clutch is engaged the feed screw revolves with the spindle, thus quickly running it up through the feed nut, and raising the drill out of the work. When clear of the work the clutch is disengaged, leaving the machine ready to drill another hole. The clutch is thrown in or out automatically by a lever engaging with adjustable stops which may be set at any point to suit the work. There is an arm on the lever by which the operator may throw the clutch in or out at any time, independent of the stops. The quick return is engaged and disengaged without stopping the machine, or throwing out the automatic feed.

Jardine Hand Drill.

Change gears provide two speeds, for light or heavy work, the slow speed giving one revolution of the spindle, to one of the crank shaft, the fast speed two and a half revolutions to one. The change is effected by two gears 28 and 40 teeth feathered on the crank shaft, and two corresponding gears 28 and 16 teeth on a quill with mitre gear which drives the mitre on the spindle. In the engraving the 40-tooth gear which crank shaft is shown engaged with the 16-tooth gear, thus driving the spindle 2 1-2 to one. The pair of gears on the crank shaft are held in position by an arm pivoted on a stud in the frame of the machine, the outer end of the arm being forked to fall over the driving shaft and act as a collar, preventing the gears from moving endways on the shaft. To change speed, the arm is raised so as to clear the gears, the gears are moved on the shaft to bring the other pair (28 and 28 teeth) into engagement then the arm is dropped on to the driving shaft, on the other side of the gears, retaining them in their new position.

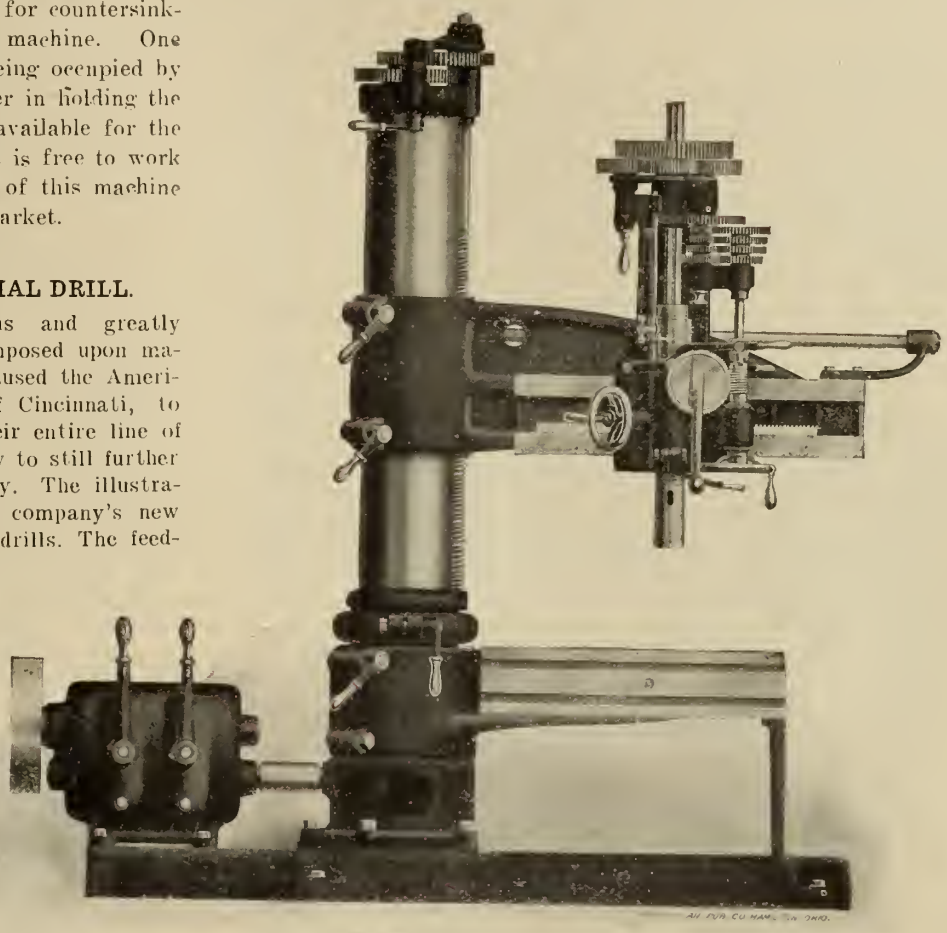
The ball bearing between the ends of the feed screw and drill spindle is held in position by the coupling, the races being of hardened steel; the lower race grooved to retain the balls, the groove being of somewhat larger radius than the balls, the face of the upper race slightly angled, forming a flat cone which keeps the balls to the outside of the centre of the groove, giving a two point bearing to the balls. The bearing is simple and effective. The table arm is held in position on the pillar by a key which occupies a recess cored in the arm. The point of the key is tapped to fit a cap screw which passes through the side of the arm. By tightening the screw, the key is drawn in between the arm and the pillar, making a quick and sure grip. By loosening the screw the arm is at once left free.

For countersinking, a treadle is used which rests on a bearing on the floor, a piece of 9-16 inch or 5-8 inch round iron of suitable length reaching from the treadle to the table arm. A key-way is cut the full length of the pillar, and

a plate with a projection which fits the key-way is fastened to the top of the table arm by a cap screw, the cap screw passing through a circular slot in the plate, the centre of the circle to which the slot is drawn being the centre of the pillar, thus when the cap screw is loosened the table arm may be swung around the pillar to any required position, and then fastened by the cap screw. The plate prevents the arm from swinging around the pillar, when the binding key is loosened, but allows it to slide freely up and down. The makers claim the foot treadle to be a much better appliance than a hand lever for countersinking on a hand drilling machine. One hand of the operator being occupied by the crank, and the other in holding the work, he has no hand available for the hand lever, but his foot is free to work the treadle. Two sizes of this machine are being put on the market.

NEW PLAIN RADIAL DRILL.

CHANGED conditions and greatly increased duties imposed upon machine tools have caused the American Tool Works Co., of Cincinnati, to completely re-design their entire line of radial drills with a view to still further increasing their efficiency. The illustration shows one of this company's new 3½-ft. arm plain radial drills. The feeding mechanism on the head provides four distinct rates of feed, covering a carefully chosen range, in geometrical progression, from .0069 in. to .0203 in. These feeds are all readily obtained by simply moving the sliding key of the feed device until the desired feed is secured. This method of feed change is by far the simplest yet devised. The all gear feeds, when supplied instead of belted feeds, insure vastly increased productive capacity, rapidity of change, and positive action. Feeds operate through a friction, which permits a drill being crowded to its limit without strain to the feed works. Feeds can be automatically tripped at any position of spindle by adjustable trip dog and pointer, acting on the worm clutch. Depth graduations are on the spindle, and all depths can be read from zero. Two or more dogs can be supplied, making it possible to counterbore any number of holes without resetting. The trip acts automatically at full depth of spindle, preventing breakage of feed mechanism. The box is of the geared friction type, providing four changes of speed, each being instantly available by use of the two levers shown. Frictions are extra powerful, employing very few parts in their construction, which can thus be made of such large proportions as to be free from slippage under the severest cuts, and obviating the use of loose delicate parts, a source of frequent breakage on most other makes of radial drills. The speed box can be easily interchanged with a cone by simply breaking a coupling connection on the lower driving shaft of the machine, base being drilled and tapped for either. A motor of any type may be attached by various methods, connection being made either direct or through gear, chain or belt. However, our experience has proven that motor on base connected by gear to 4-speed box is the most simple, efficient and serviceable method. Drive "G," in the booklet, illustrates this method. The spindle has eight changes of speed, ranging from 37 to 295 in geometrical progression, all immediately available without stopping the machine. This wide range of spindle speeds, combined with the exceptional driving power of the machine, renders the drill equally efficient with either ordinary or high speed twist drills. The column is of double tubular type. Sleeve or outer column revolves around a central column and is clamped to any position by our patent V clamping ring. This makes the outer column practically integral with the inner column, which extends almost the entire height, and has bearing for outer column at both top and bottom. This gives the equivalent of a double column, affording exceptional rigidity. Arm is of parabolic beam and tube section, giving greatest resistance to bending and torsional strain. Its design leaves the lower line parallel with the base, and thus permits work being operated upon in close proximity to the column without the necessity of an extreme reach of spindle. Arm is clamped to column by two binder levers, obviating loose wrenches, and is raised and lowered rapidly by a double thread coarse pitch screw, controlled instantly by a convenient lever. Head is moved rapidly along the arm by hand-wheel



New Plain Radial Drill.

through angular rack and spiral rack pinion. It has convenient clamping lever for locking it in any position. Back gears are located on the head, the only proper place for them, thus bringing the greatest speed reduction direct to spindle. They may be engaged or disengaged without shock or jar while the machine is in operation. Spindle is counterbalanced and has frictional quick advance and return. Tapping mechanism is carried on the head, between the back gears and speed box, thus giving to the frictions, already very powerful, the benefit of the back gear ratio, making unusually heavy tapping operations possible, and also permitting taps to be backed out at an accelerated speed. The lever for starting, stopping, or reversing the spindle is controlled at the head from the front of the machine.

Imperial Plug Driller.

THE IMPERIAL PLUG DRILLER.

THE Imperial Plug Driller is the most recent production of the Canadian. Rand Drill Co., Sherbrooke, Que. Already this tool has won for itself an enviable reputation among miners, quarrymen and contractors, and bids fair to revolutionize present methods of rock excavation. A glance at the construction of the tool will readily convince one that its lightness and compactness, coupled with the comparatively small consumption of air, fit it for the work which it is designed to do. While primarily intended for the lighter work of rock excavating, such as putting in plug and feather holes, stoping, squaring up, sinkink pop holes, drilling anchor holes and similar work, owing to its handiness, the tool is sure to find unexpected uses.

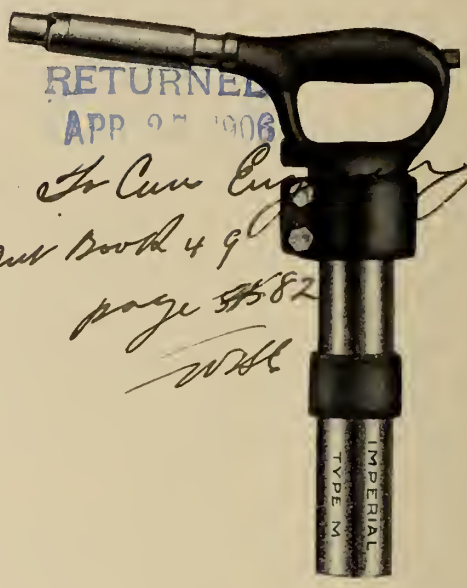
THE LARGEST ROCK CRUSHING PLANT IN THE WORLD.

THE Power & Mining Machinery Co., of Cudahy, Wisconsin, (suburb of Milwaukee) has recently closed a contract for a complete rock crushing plant to be erected for the Little Falls Stone Co., Little Falls, New York. This plant will embody all of the latest ideas in modern crushing practice and will be built throughout in accordance with designs made by the Power and Mining Machinery Co.

One feature in connection with the equipping of this plant that will be of more than usual interest, will be the enormous size of the main crusher, a No. 10 McCully, the largest machine of its kind ever designed or built. To form anything like a true conception of the immense size of this crusher, it is only necessary to state that its weight will be nearly 200,000 pounds and its capacity, under favorable conditions, 700 tons of crushed stone per hour, or 7,000 tons per every working day of ten hours. The product from this plant will be used for ballast, railroad, and concrete work. All of the dust or fine material accruing from the crushing of the stone is to be used for making cement bricks, the manufacture of which will be carried on in a near-by plant owned by the same company.

BUFFALO SHEAR.

THE accompanying cut illustrates the slitting shear, made by the Canadian Buffalo Forge Co., Limited, of Montreal. The body is of heavy armour plate and for this type of shear is



RETURNED

page 582
Ans

made in two pieces which are bolted together with a joint that gives clearance of the sheet beyond the blades. It has an easy capacity of No. 8 gauge and larger sizes are made for heavier plate. As this type of shear blade is not suitable for cutting bars, an attachment will be noted in the body of the punch which is for this purpose above. The No. 4 1-2 B. combined punch and shear stands

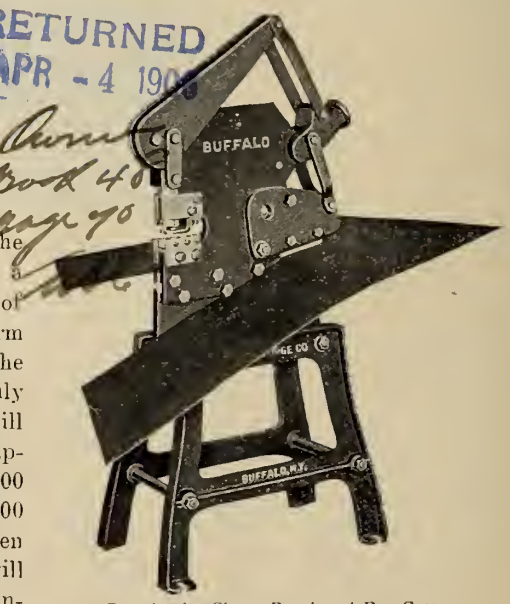
Our Book 49
page 70



Combination Shear, Punch and Bar Cutter.

48 inches high, and weighs 375 pounds. The height from floor to die is 29 inches, with stand, and if required for use on a bench or block, an allowance is made by manufacturers for the stand, and the

angles at the base of the plate are drilled for holding down bolts.

The punch end of this machine has a capacity of a 5-8 inch hole in 1-2 inch plate, and the depth of throat is 5 inches. A large machine called the No. 5 Buffalo Giant punch and shear has a capacity for a 3-4 hole in 1-2 inch plate. Independent punches, independent shears, and combinations of various sizes give a large choice in selection The pygmie shear shows the form of the smallest size, which is capable of handling 1-8 inch stock.

GIGANTIC TESTING MACHINE.

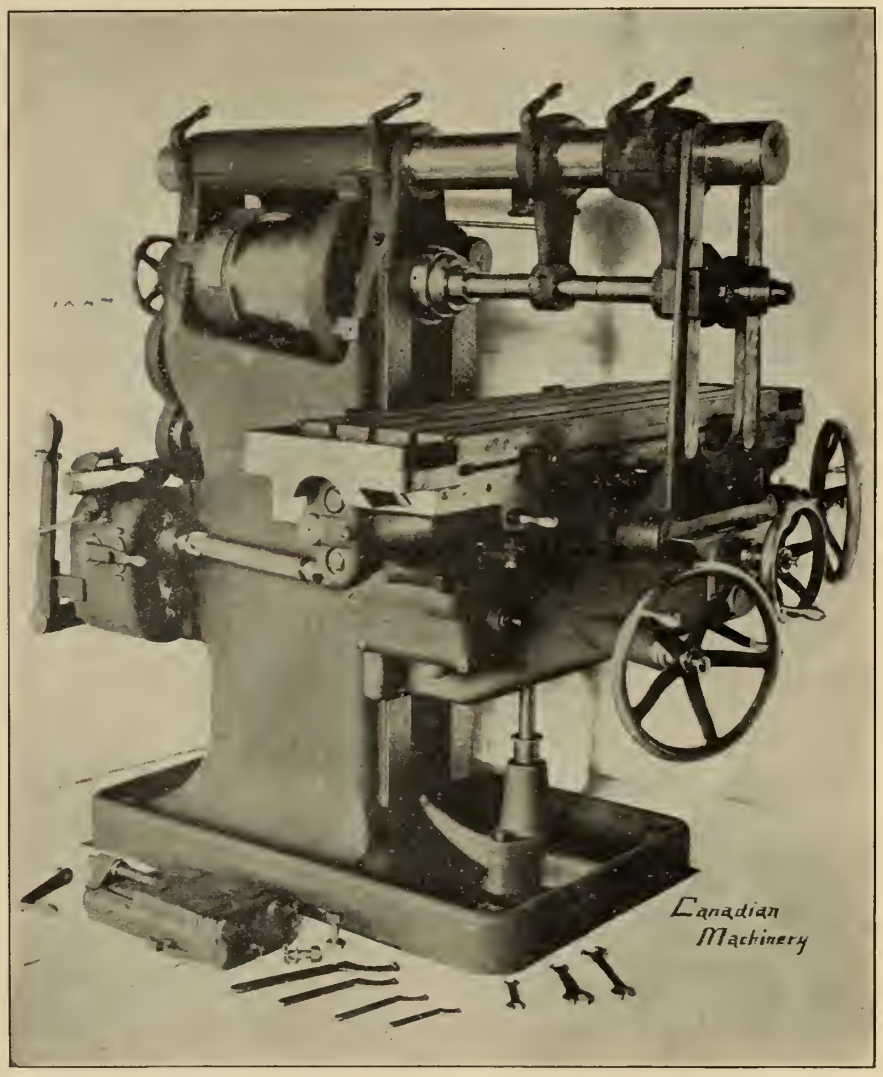
W. & T. AVERY, LIMITED, of the historic Soho foundry, Birmingham, where so much pioneer work has been done, have now under construction for the Birmingham University, engineering section, a huge machine for testing whole members of constructional work, such as complete girders, columns, and every part in the construction of bridges, roofs and machinery, in fact, the machine will test any and every part that can possibly be used in engineering work. The machine is designed to test specimens for tension, compression, and transversely. The maximum capacity is 300 tons, the total length 70 feet, and the weight of metal in the machine is about 85 tons. The machine is driven by hydraulic power, and the adjustment for testing from the largest specimen, 30 feet long, down to the smallest, is made by an electric motor, working at 750 revolutions per minute.

The machine is one of the largest testing machines that has ever been made, and is specially comprehensive, in order to give the whole range of tests. The machine is so arranged that an official can govern from one position the hydraulic power applying the strain, the electric power by which the various adjustments are made, also the recording steelyard. This machine will be a splendid acquisition to the Birmingham University, and to the City of Birmingham. A machine which will test whole members of constructional work is of special interest at the present time, as such tests should help materially to avoid in the future, such catastrophies as the recent one at Charing Cross.

PLAIN MILLING MACHINE.

IMPROVEMENTS have recently been made in the No. 4 plain milling machine built by the Becker-Brainard Milling Machine Co., Hyde Park, Mass., of which an illustration is shown herewith. Probably the most important of these is the positive gear feed drive and change feed mechanism, by which 20 changes of feed can be made without stopping the machine. The clutch mechanism in connection with the handwheels is also new, as well as the box type of knee and the telescopic elevating screw.

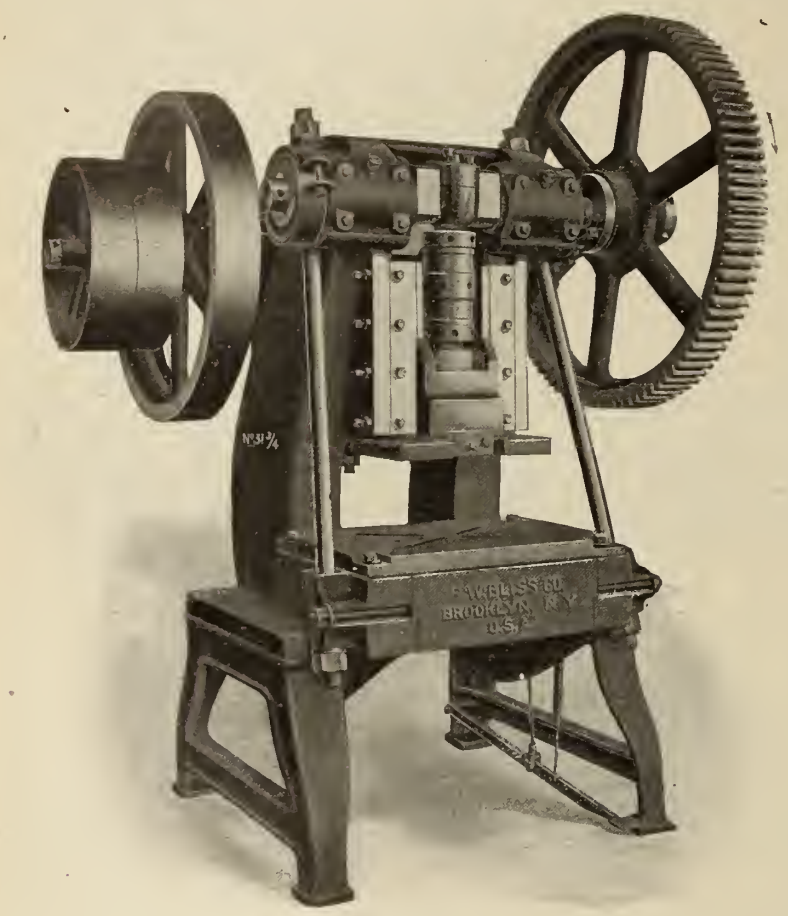
The spindle is of hammered crucible steel, has a 3-4 inch hole through it and runs in self centering bronze boxes arranged to compensate for wear. At the front end the spindle has a No. 2 B. & S. taper hole, a slot across the end to engage a clutch, the arbor and a thread to take a chuck. This screw is covered by a collar when not in use. The spindle is connected with the change feed mechanism by three spur gears, making a positive driven feed. It is double back geared, the gears being protected with shields. The arm is of steel, is arranged to adjust horizontally and has a removable arbor support, allowing the use of any attachment without removing the arm. The platen has automatic longitudinal, cross and vertical feeds. It is provided with T slots and oil pans at each end. The feed may be reversed at the front of the machine. The knee is provided with an automatic vertical feed and knock off. The hand wheels for operating the feeds have clutch members inclosed in their hubs. When the table has been set to the required position the clutch may be instantly disengaged by pressing in a knob on the front of the hand wheel. This prevents any accidental change of position of the work and avoids the revolving of the hand wheels when the feeds are in action. To indicate the vertical, transverse and longitudinal movements of the platen there are adjustable dials graduated to thousandths of an inch, which may be set at any position with set screws.



Plain Milling Machine

A NEW BLISS COMBINATION PRESS

HEREWITH is shown a new combination press useful for a wide range of sheet metal work. Besides being of a heavy and massive construction, it is fitted with stay rods, which give extra strength and rigidity. It has a cap and flange mandrel, so that the small combination dies may be fastened into the slide by their stems or the larger cutting or blanking dies may be bolted on the flange. It is usually furnished with a combination die bolster, such as is desirable in operating combination cutting and stamping dies. The front of the press-bed is removable so that a sunken bolster, a horn frame with horn or a wiring frame with slide plate may be substituted and the press be used either for closing side seams or for wiring the top edges of sheet metal bodies. The press is particularly adapted to the manufacture of enameled ware, pieced tinware, powder cans, canisters, pails, buckets, pans, etc., and may also be arranged for petroleum, biscuit and varnish cans and other square work by substituting horns of the proper shape.



New Bliss Press.

Some of the important dimensions are: Width between uprights, 16 inches; opening in bed, 16 1-2 x 25 inches; distance back from centre of slide, 12 inches; distance from bed to slide, stroke and adjustment up, 12 inches; standard stroke, 4 inches; strokes, 75 to 100 per minute; height centre of shaft, 71 1-2 inches; floor space over all, front and back, right and left, 72 x 75 inches. This press is built by E. W. Bliss Co., 20 Adams street, Brooklyn, N.Y.

INVENTION FOR MAKING STEEL.

Two important inventions in the manufacture of steel have been brought to the attention of manufacturers in Pittsburg recently, which may have a far-reaching influence on the future steel trade. One is along the lines of economy in production, and is the idea of Ralph Baggelev, of Pittsburg, who has worked out a model of an open hearth furnace, from which the gases generated from the burning metal are carried off from the furnace and over a screen, which is so constructed as to catch and retain all the iron sulphur and other impurities in the gas. The screen soon becomes fully loaded and is replaced with another. The loaded screen is divested of its load, and from the mass is extracted the sulphur which becomes a commercial commodity, and the rest, which is a slag, is used in furnaces and reduced to iron, thus saving a waste that in the long run is enormous.

The second invention is a process designed by a Cleveland man, Horace W. Lash, who has conceived the idea that by mixing the molten mass of a blast furnace running on any low-grade ore, after one portion passes through an acid-lined Bessemer converter and is blown free of silicon and other impurities and the other portion has been poured into a basic open hearth. The action of mixing the two bodies of molten metal, it is claimed, will result in making the highest grade of steel, for it will be equally carbonized and because of the large size of the charges, it will become dephosphorized by natural rules.

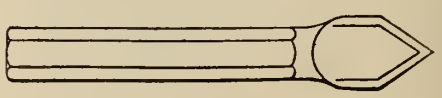
The value of the latter will be to make available all of the vast stores of low-grade ore that are found all over the country and within easy reach for the higher grades of steel. The process will also cheapen the production of steel. Both patents have been taken up with interest by large corporations for further development and from the manner in which they are studied the results will be of the utmost interest within the next year.

The utilization of the immense deposits of low-grade iron ores scattered all over the North American continent has been a dream of the steel manufacturer for years. Heretofore, the only ore suitable for the economical manufacture of steel has been confined to the Lake Superior regions, and this is now practically all controlled by a few allied interests and its quantity is so closely estimated that the life of the beds has been figured to a nicety. To extend the steel-making ores to all beds would put the end of such ores so far into the future as to practically make them inexhaustible.

HANDY MARKING CHISEL.

A MARKING chisel is a convenient tool about the engine room. One of the instances in which it can be used to advantage is in marking the eccentric so that it can be readily reset should it slip on the engine shaft.

It is often difficult to mark the eccentric and the shaft so that the lines come exactly opposite. With the tool illustrated this is made easy. The cutting edge is made as shown and not at right angles with the side. The point strikes first and makes a true mark on the eccentric hub. By turning the chisel in the opposite direction a mark is made on the engine shaft.—Engineers' Review.



Marking Chisel.

INDUSTRIAL PROGRESS

MACHINERY AND MANUFACTURING NEWS would be pleased to receive from any authoritative source industrial news of any sort, the formation or incorporation of companies, establishment or enlargement of mills, factories or foundries, railway or mining news, etc. All such correspondence will be treated as confidential when desired.

Edmonton will spend $180,000 in civic improvements this year.

The C. P. R. pier at Quebec will be extended another 358 feet.

The Edmonton Tent & Mattress Company will build a new factory.

The Imperial Plaster Co. will erect a large grinding mill at Cayuga.

H. K Wampole & Co. will erect a box factory this year at Perth, Ont.

The Le Roi mine at Rossland, B.C., made $39,000 profits in January, 1906.

The London Fence Company will build a fence factory at Portage La Prairie, Man.

A new light and power station is about to be built in the town of Chatham, N.B.

F. B. Moffat, of Enderby, B.C., is preparing to erect a flour mill at that point.

The Montreal Mining Exchange are considering the question of holding daily sessions.

John Hinds, of Barrie, has reported making a valuable find of mica near Carney, Ont.

Work has commenced on rebuilding the C. P. R. burned freight sheds at Winnipeg.

Smith & Sherbourne have started building the Carter-Cotton building at Vancouver.

D. A. Vaughan, of St. Stephens, N.B., will build a paper box factory at Sussex, N.B.

The Twin City Brick Co., Port Arthur, Ont., are making a large addition to their plant.

The Little Bay copper mine in Newfoundland is being examined with a view to opening it up.

The Montreal Street Railway Co. will spend $750,000 in the construction of new rolling stock.

The Whitewood Implement Company are building an implement warehouse at Whitewood, Sask.

King & Crosby, Hamilton, Ont., are working on a drill which is to have several new features.

The proposed power plant for the corporation of Morrisburg, Ont., will shortly be commenced.

The Canadian-American Coal Company will spend $60,000 on a tipple and other improvements at Frank.

At the annual meeting of the Hamilton Gas Light Company a dividend of 8 per cent. was declared.

The International Brick & Tile Co. ask for tenders for the sale of their plant at Bridgetown, N.S.

The Montreal Light, Heat & Power Company will build a new office building to cost over $100,000.

The Dominion Iron & Steel Co. have begun to manufacture steel rails for the Canadian Pacific Railway.

The United States Steel Corporation has nearly 175,000 employees, one fifth of whom are stockholders.

The Manitoba Iron Works, Winnipeg, invite tenders for erection of boiler house and structural iron shop.

The Felt Roofing Company will build a new factory at Brantford, with a capacity of 25 to 30 tons a day.

The largest steel ingot that has ever been made has just been cast at Manchester, Eng. It weighed 120 tons.

The Lansdowne Park Improvement Company will erect a cement block show building at Ottawa to cost $45,000.

J. M. Gardiner, Chatham, and Wm. Milner, of Petrolia, are promoters of an auto factory to be built at Chatham.

The Cataract Power Co. will build new car sheds at Hamilton for the Radial, the street railway and the T. H. & B. roads.

An oil strike was made near Aylmer while boring for water. It is said to pump three barrels of lubricating oil per day.

The city of Calgary is advertising for industries to locate there and offers inducements in the way of power and light.

G. E. Fisher and J. D. Johnston, of Chatham, are at the head of a company who will build a grist mill in that town.

The Quebec-Jacques Cartier Water Power Company will either acquire the Quebec Gas Works or will build a new plant.

The Smith's Falls Foundry and Malleable Company has changed its name to the Rideau Malleable & Foundry Company.

The town of Smith's Falls will give a loan of $150,000 to the Frost & Wood Company to help rebuild their burned shops.

The contract for a spinning mill for the Eagle Knitting Company at Hamilton has been let. The cost will be about $30,000.

The Arbuthnot Fuel Company, of Winnipeg, has been declared insolvent, and application has been made for a winding up order.

The Borland Carriage Company, of Stratford, will build additions to its factory shortly which will double its capacity.

A site has been purchased in Berlin for the installation of a cement brick plant. J. Thussier, of Parry Sound, is the promoter.

The Imperial Oil Company will shortly commence the erection of a candle factory in Sarnia. It will be three storeys high, of brick.

The Lake Superior Corporation has adopted plans for new open hearth furnaces at the Soo, and contracts are about to be let.

The Peterboro. Sandstone Brick Company will commence work on their new plant and expect to be turning out brick by May 1.

The Toronto Board of Control has under consideration the purchase of the Erindale plant of the Southern Light & Power Company.

The by-law to raise $15,000 to establish an electric light plant in the town of Carberry, Man., has been carried by a large majority.

Cayuga, Ont., ratepayers carried a by-law to raise $5,000 to purchase 50 acres of land for the Pittsburg Window Glass Machine Company.

The Imperial Bank have opened a branch in Red Deer, Alberta, and also contemplate opening branches in Quebec, London and Banff.

S. R. Rudd, of Arnprior, has been awarded the contract for the erection of a shirt factory to be operated by a Montreal company.

Toronto building permits for the first two months of this year amounted to $836,000, as compared with $594,000 for same period last year.

The value of mineral products for 1905 in Canada was $68,574,707. Coal amounted to $17,000,000, copper $7,420,451, lead $2,634,084.

Seaman, Kent & Co., Meaford, Ont., have placed their third order within two years for a Cumber dry kiln with Sheldon & Sheldon, Galt, Ont.

Plans are being prepared by the city engineer, Edmonton, Alta., for three miles of street railway, which it is proposed to build this Summer.

Gibson & Company's roller mill at Morrisburg was destroyed by fire on the 20th inst. The loss is about $25,000, partly covered by insurance.

The Canadian Flax Cordage Company purpose building a factory at St. Mary's, Ont. The town is surrounded by a good flax-growing district.

Walkey Bros.' furniture factory, Fordwich, Ont., was destroyed on the 20th inst. by fire. The loss is over $5,000, covered by insurance of $2,700.

The Edmonton council reported in favor of giving the C.P.R. $25,000 on condition that the shops for the northern extension be located in that place.

The Indestructible Fire Brick Company, who have been busy installing their plant at Mimico, expect to employ ninety men when in full operation.

M. P. MacNeil & Co., of New Glasgow, N.S., have secured contracts for erecting buildings for the Acadian Coal Company to the value of $50,000.

Upon the completion of their smelters at Port Arthur, MacKenzie & Mann will probably erect rolling mills there, similar in size to those at the Soo.

The Department of Trade and Commerce announces that the bounty on lead is still suspended, as the price continues a shade over the bounty figure.

Amherst, N.S., will expend $80,000 on local improvements, including extension

of waterworks and sewage systems, and additions to the Winter Fair buildings.

A very rich peat bed has been discovered near Schomberg, Ont., on the line of the Trent Valley Canal extension, and a company will be formed there to work it.

The Great Northern Railway is said to be surveying for a line to run northwest from Burnha, Montana, to Medicine Hat, Alta., and from thence to Edmonton.

It is stated that Chas. J. Coll, of the Acadia colliery, Stellarton, N.S., has purchased the coal areas of the Cumberland Coal & Railway Co., located at Broughton.

Capt. P. N. Thompson, Vancouver, has applied for thirty acres adjacent to Nairn Falls, on the Green River, for the purpose of developing a waterpower there.

The Canada Plate Glass Company suffered loss by fire on Tuesday last to the extent of $15,000. The fire occurred in their Richmond street, Toronto, warehouse.

The Lake of the Woods Milling Company have plans completed for the building of two more mills this year, one at Montreal and the other at some point in the West.

The Peacock File Co. intend removing their entire plant from Buffalo to some point in Canada. They employ about fifty hands and may locate at Port Colborne.

A charter is being sought for the East Toronto and Danforth Electric Railway Company, which purposes building a line from East Toronto to St. Lawrence Market.

The Chas. Fawcett Manufacturing Co., of Sackville, N.B., will build an addition 65 by 120 feet to their molding shop, and will also enlarge their steel range building.

Hamilton citizens are discussing an electric railway from Hamilton to Guelph Junction for the purpose of a more direct lake connection with Goderich and Owen Sound.

Macleod, Alta., is looking forward to a busy season in building. A grist mill, a storage plant and the new Hudson Bay stores are among the larger buildings to be erected.

Blairmore, Alta., is to have a bottling works. The plans call for a solid stone building 25 x 50 feet. The Rosse building has been started, and other buildings are contemplated.

The Vancouver, Fraser Valley & Southern Railway Co. will ask incorporation at the next session of Parliament to build an electric railway from Vancouver to New Westminster.

The Roberts Heating & Ventilating Co., of Minneapolis, intend to erect a warehouse and branch factory in Winnipeg during the coming Summer, to be valued at $20,000.

W. H. Banfield & Sons, Adelaide street, Toronto, have increased the capacity of their plant during the past month by a further addition of up-to-date machine tools.

The Grand Trunk has secured an option on the Cowey block, Ottawa, for $225,000, and if the deal goes through they will pull down the building and use the land for terminals.

Agents of J. J. Hill are spying out the land in Saskatchewan and making large purchases. It is said this is only part of a project to build a line from Lethbridge to Winnipeg.

It is understood that Heinze, the Montana copper king, has secured working options on forty British Columbia mines, and that a smelter will be in operation within a few months.

The contract for grading the Midland Railway of the Great Northern system from Portage Le Prairie to the international boundary has been let to the Guthrie Company of St. Paul.

Carberry, Man., will build and own its own electric light plant, which will cost about $12,000. The building will be such that it can be enlarged should the town decide to also own its telephone.

Thirty members of the Canadian Manufacturers' Association have already applied for space at the New Zealand International Exhibition which will open at Christchurch in November next.

The Hamilton Pattern Works have completed the installation of the equipment of their pattern shop on Bay street, Hamilton, Ont., and are already finding a demand for their services.

The work of developing power from the Kakabeka Falls, 16 miles west of Fort William, is nearing completion, and by the 1st of June, 1906, electrical energy will be supplied to the twin towns.

The total output of British steel ingots for 1905 was 3,879,000 tons, an increase over the previous year of 634,000 tons. The principal finished product of this industry is for shipbuilding.

The Vancouver Furniture Manufacturing Company will commence operations next month. The factory will use native woods and will be 50 by 100 feet in size. Machinery is now on the way from the east.

A Manitoba blacksmith is said to have discovered a chemical process for tempering and welding copper. A. McMillan, of Winnipeg, has secured patent rights for this method in Canada and other countries.

The by-law granting a 99-year franchise to the Western Power Company of Brandon has been reconsidered, as an act of the Legislature prohibits the granting of such franchise for more than 30 years.

The Montreal Power Company have plans to place a considerable portion of their wire underground. They will commence work as soon as the frost is out of the ground, and will expend this year $100,000.

Greenshields & Greenshields, of Montreal, have made an offer on behalf of unknown clients to lease the New Brunswick Coal & Railway line and rolling stock for 999 years at an annual rental of $21,000.

A large brick yard is to be established at Melfort, Sask., by a Toronto company with which E. Hawke is connected. It is also announced that the Standard Oil Company will build a warehouse there.

The Pupay Electric Meter Co., of Peterboro, Ont., are having the first of their meters tested after which they purpose going into the manufacture of this new and promising line on an extensive scale.

The Peterborough Sandstone Brick Co. have purchased a carload of machinery for their plant, and upon its arrival will go right ahead with the work of getting everything in operation to meet the season's trade.

The Brandon Electric Light Company are preparing to make large extensions to their plant at Brandon, Man. A new brick station will be erected in which modern boilers, engines and generators will be installed.

Greer Bros., of Port Arthur, have secured the contract for supplying 2,000,000 ties for the new transcontinental railway, to be delivered this Summer. This is the largest contract of its kind ever given in Canada.

The Lake Superior Co., Sault Ste. Marie, Ont., will build a large addition to their steel works. A building 200 by 110 feet will be erected. The new furnaces will cost some $250,000. A coke plant will also be installed.

The Government of Nova Scotia will assist in the building of a railway from Halifax to Guysboro by giving a loan. Sir Montague Allan, of the Allan Steamship Line, is at the head of the syndicate who will build the road.

The smelter of the Granby Copper Co. is making a record run, treating about 2,800 tons of ore daily. The management is enlarging the furnaces and expects to increase the smelter capacity to 3,000 tons per day.

The Lakefield council have decided to submit a by-law to the ratepayers regarding the taking over of the Lakefield Light & Power Company's plant at the price of $5,500, also the raising of $2,500 for improvements to the plant.

Contracts are about to be let by the Lake Superior Corporation for the construction of a new open hearth blast furnace, to cost $250,000. It will have a capacity of 200 tons a day, and will be in operation within six months.

The Canada Foundry Company is arranging for large extensions to its Peterboro plant. The new allotment of 11,000 shares of stock has been all subscribed for. In all there are nearly 1,000 shareholders in this company.

The net earnings of the Temiskaming Railway for 1905 were $113,772, the percentage of gross earnings to operating expenses being 55 per cent. Track-laying northward is now going on and they expect to reach Black River by June 1.

The new taxes to be imposed by the Quebec Legislature will include all kinds of corporations, in varying amounts according to their capital stock. A tax of five dollars will also be levied on automobiles and a like amount on licensed chauffeurs.

The Dominion Public Works Department will call for new tenders about

April 1 for the proposed dam and locks at St. Andrew's Rapids, Man. Owing to the high water of 1904 the original plans have had to be altered to meet such exigencies.

Hon. Mr. Emmerson has announced that the Intercolonial railway shops, which were destroyed by fire, will be rebuilt, and that plans are already under way. Temporary shops will be put up at once.

The North Atlantic Collieries Co. have plans under way for development work at Port Morien, C.B. Messrs. Hyde and Patterson have been looking over the site with a view to contracting for the sinking of the shaft.

The Southwestern Traction Company, of London, are negotiating with the Ingersoll Town Council for the privilege of entering the town in connection with the electric railway line which they intend building from London to Hamilton.

The miners of Galt coal in Southern Alberta have asked for a minimum wage of $3 per day of eight hours. recognition of the union and the right to employ check weighers. The managers will confer with the men. but are averse to making the concessions.

The Brintin Carpet Factory, of Kidderminster, England, which intends establishing a carpet factory in Canada, has about concluded negotiations to locate in Peterboro. The company will employ about 75 hands and will be given a site and exemption.

At the annual meeting of the Bell Telephone Co. it was decided to increase their capital stock from ten to fifty million dollars. It is the intention of the company to strongly oppose the movement in the west, for a Government-owned system of telephones.

Fred. Hobart, of New York, in the course of a speech at the Mining Institute banquet, in Quebec, stated that it would not be long before the United States would have to look to Canada for their iron, as the American ore was becoming rapidly exhausted.

The council of the Montreal Board of Trade has decided to send a delegation to England to attend the sixth congress of the Chambers of Commerce of the Empire. The delegates will be F. H. Mathewson, Geo. L. Cains, George E. Drummond and George Hadrill.

The Quebec Southern Railway will be extended from St. Francois to Chaudiere Junction, and it is expected that the road will be in operation as far as Becarcour by the month of September. From there to Chaudiere will require several more months to construct.

The Terminal City Ironworks is the name of a new firm which has opened up for business in Vancouver. They make a specialty of handling engine and machine repairs. The new firm is composed of H. J. Littler, T. W. Littler and J. Mason, all practical men.

The city of St. John, N.B., will ask the Legislature for power to take a lien for taxes on the property of deceased persons, and bankrupt estates. They will also seek power to buy or expropriate the gas plant operated by the Street Railway Company, and to operate street railways in Cardston, a section of the city where there are no lines.

Calgary city council has decided to submit a by-law to the people to raise $100,000 to improve the waterworks, and $30,000 to extend the electric lighting system. The council also decided to assist manufacturers employing over twenty-five men, by tax exemption.

The Anthony Wire Fence Co., who have been operating in Windsor for some time past, have been receiving offers from other points to induce them to leave. Unless Windsor makes certain concessions it is probable that one of these other offers will be accepted.

Building permits for January and February in Winnipeg amounted to $328,000. Some of the principal buildings to be put up this year are the new Grain Exchange, Bank of Hochelaga, city crematory addition, jail, besides several churches and business blocks.

Railway supplies, such as crossings, switches, etc., will be manufactured in Niagara Falls, Ont., by a Canadian branch of Ramapo Iron Works. Besides the Americans interested are J. W. Nesbitt, J. G. Gauld, Jas. Dickson, R. O. Mackay and A. B. Mackay, of Hamilton.

Sheldon & Sheldon, Galt, Ont., have supplied the Don Valley Pressed Brick Works with a brick drier with a capacity of 37,000 bricks a day and have installed a kiln for drying brick with the waste gases from the burning tanks in the works of the Laprairie Brick Co., Montreal.

The International Railway Company, of Buffalo, and the Toronto Railway Company purpose building an international bridge on the Niagara River below the Falls. The purpose of this bridge is the connecting of Buffalo and Toronto by a double tracked electric express line.

A company with $5,000,000 will develop the following mining interests near the boundary in British Columbia : War Eagle, Bald Eagle, Lulu, Red Rock, Missing Link No. 2, Pinhook, World's Fair and Dandy. The new company will be known as the Phoenix Amalgamated Copper Mines.

The decision of the C.P.R. shareholders to increase the capital stock of the company from $110,000,000 to $150,000,000 shows a commendable optimism and belief in the future of the country. It was announced at the meeting that the earnings during the current year would reach $60,000,000.

Canadian locomotive imports from the United States fell from $1,353,331 in 1904, to $363,524 in 1905, most of the Canadian locomotives being manufactured at home. Steel rail statistics are much the same, now that the iron and steel industries in Canada have reached such development.

The output of copper by the Granby Mining Company now averages 2,000,000 pounds per month. The furnaces are being enlarged, which will increase the smelter capacity to 3,000 tons a day. The net earnings of this company are at present equal to 15 per cent of the common stock.

A company to manufacture soda ash will seek incorporation from the Dominion Parliament. The promoters have been quietly at work for some weeks and have secured between fifty and sixty acres of salt lands near Sandwich, Ont., and also some lime lands. They will be capitalized at $1,000,000.

The Tarbrock Iron Mines in Annapolis county, Nova Scotia, are about to pass into the hands of a syndicate of Montreal and Toronto men for a consideration of $250,000. It is expected that when the new corporation gets full control the capacity of the mine will reach 1,000 tons of ore per day.

The management of the Canadian Pacific Railway have authorized the building of a thousand box cars, of the ordinary thirty-ton type, for use on the company's system. These cars, which are to be built at the Angus shops, represent an expenditure of between eight and nine hundred thousand dollars.

H. W. Petrie, who has been in the machinery business in Toronto for thirty-five years, has opened up a branch in Montreal. They will carry all kinds of engines, boilers and machinery in the Montreal branch, which will be in charge of A. W. Royan, late of John Bertram & Sons.

The parliamentary committee of the Canadian Manufacturers' Association will interview the Ontario Government with a view to amend the Assessment Act, by which they claim land tax is made excessive. The wage earners will also, through their organizations, protest against the income tax.

About 2,000 miles of railway will be tracked or graded in Canada during 1906. The Grand Trunk Pacific contracts call for the construction of 1,000 miles, the Canadian Pacific Railway Company's contracts call for between 400 and 500 miles, and the Canadian Northern Company's for a similar mileage.

Mr. N. Dyment, and A. E. Dyment have sold their timber limits, and their sawmill and shingle factory at Thessalon, to a United States syndicate for the sum of $650,000. The purchasers are E. P. Nesbitt and Geo. Nestor, of the Nestor estate, Detroit, and W. Bishop, of the Laney, Bishop Lumber Co., Chicago.

At a recent meeting of the Montreal Chambre de Commerce, the advisability of imposing a tax on United States contractors doing business in Canada was discussed. It was stated that Canadian contractors had to pay a tax in United States. The matter was referred to the committee on industries and manufactures.

Senator Domville, who has just returned from England, has made the announcement that $20,000,000 of British capital will be invested in the Canada Central Railway. It will run from Montreal to Ottawa and thence westward between the lines of the Canada Atlantic and the Grand Trunk to Orillia.

A modern steel plant is to be established at Grand Forks, B.C. Contractor M. S. Martin has the contract for the erection of the building, which will be 40 x 60 feet, and will be built in connection with the Boundary Iron Works.

The plant will turn out all kinds of steel work and will employ some ten men to start with.

The annual report of the Crown Timber Office for Winnipeg district during the fiscal year of 1904-5 shows large increases in the sales of Canadian manufactured lumber, and a corresponding decrease in the amount imported, the sawn lumber from the United States falling to one-half the former importation.

Welland, Ont., looks to a large year in building for 1906. In addition to the Plymouth Cordage Works already under construction there will be a new steel and iron works to cost $100,000, buildings for M. Beatty & Sons Co., and Robertson Machinery Company, besides extensions of the electric railway, Government drain and town waterworks.

The Brandon Electric Light Company are making large extensions to their plant in order to supply the increasing demands for power from manufacturers. They will increase their lighting and power plant by 600 h.p. and have made arrangements for the building of another power-house. It is expected that the new plant will be in operation about August 1.

The Canadian Pacific Railway has paid the Province of Quebec seven million dollars, being the amount in full of their indebtedness for the purchase in 1882 of the Quebec, Montreal, Ottawa & Occidental Railway from the Chapleau Government. The C.P.R. has been paying 4½ per cent. on this debt, but have now been able to negotiate a loan at a more advantageous rate.

New Zealand has begun to use the wood stave water pipe made in British Columbia from the famous Douglas fir. A representative of the Canadian Pipe Co., of Vancouver, made a visit to the colony last Fall, and as a result has recently closed a very large order, comprising some 30,000 feet of 16-inch pipe, and fully as much more of other sizes, 6-inch, 8-inch and 19-inch.

The Buskard Gas Engine & Machine Co., Limited, Hamilton, Ont., has been organized by S. G. Buskard, George Schnobel and Daniel Sullivan, to manufacture gas engines, brick and cement block machines and cement mixers. Mr. Buskard has given his time for many years to the development of his gas engines and expects to place on the market one which will combine efficiency and simplicity to an exceptional degree.

Many machine shops throughout Canada seem to be realizing the advantage of manufacturing a standard line and working up a demand for it. St. Clair Bros., Galt, Ont., have started to make machine handle forgings and are so satisfied with the experiment that they are making arrangements to manufacture other standard lines. This firm is also making the Griffin mill, for cement making, for the Senator Mills Mfg. Co., of Galt.

Twenty thousand horse-power is to be developed from Lillooet Lakes, B.C., by the Burrard Power Company, who will build a plant at Port Haney, on the Fraser River. It is said that on account of the elevation of these waters—four hundred feet above sea level—a reservoir will be unnecessary, the natural discharge being sufficient. The area of Lillooet Lakes is about forty-five hundred acres, and the watershed feeding them is very large.

Bradstreet's in Calgary.

The Bradstreet Company, who have had a representative stationed in Calgary for some time, have decided to open a fully equipped office in that city. This move on their part is greatly appreciated not only by the local bankers and wholesalers, but also by all that trade which is more or less tributary to Calgary.

MacGregor Gourlay's New Works.

Much speculation has been indulged in by the daily press regarding the intentions of the MacGregor-Gourlay Co., Galt, Ont. A notice to the effect that this company has found their premises too small and that they were ready to sell their present machine shop and build new works had appeared in the local press. Since, it has been stated several times that they had reached one decision or another.

A few days ago, however, a representative called to secure definite information regarding their intentions. Mr. MacGregor, in reply to inquiries, said: "You may say that we need to increase our production, that we hope to erect new works, but that no decision whatever has been reached regarding the matter."

First Automobile Show.

The first automobile and motor boat show to be held in Canada is to be opened at the Granite Rink, Toronto, on March 31 and will last until April 7. Every effort has been made to make this show a complete success and present indications would show that such is already assured. A large collection of domestic, American and English cars will be shown. The Automobile Club is very enthusiastic in the matter and the extent and completeness of the show will no doubt be a surprise to many.

Boiler Interests Combined.

A $15,000,000 company has been formed by combination of the interests of the Babcock & Wilcox Co. of the United States and the Consolidated Boiler Co. Both companies make water tube boilers for stationary and marine use and conduct a large export trade. In the past they have been strong competitors for foreign trade and this combination thus brings together the manufacturing facilities of two of the largest makers in the world. This merger will not affect the Canadian interest of Babcock & Wilcox, Limited, as the Canadian branch is connected with the Glasgow company which has a different organization from the American firm.

London Machine Tool Co. in Hamilton.

With their handsome and modern factory building completed, the London Machine Tool Co., of Hamilton, have moved their equipment besides installing a large amount of new machinery in their Hamilton plant. It is situated in the new industrial quarter of that city, and is equipped to manufacture with the greatest facility. Electric power at a low rate is available here. The plant is so designed that extensions may be made and with the growing business of this firm it is expected that such will materialize before long. A noticeable feature in the interior is the abundance of light that is so evenly distributed, making strong shadows entirely out of the question. All the modern heating and ventilating facilities have been adopted as well as individual motor drives for the machine tools and a complete equipment of traveling cranes and auxiliary apparatus. A railroad siding enters the main building, connecting directly to the main line, thus rendering the loading and unloading of goods a simple matter, as the floor on which the track enters is covered by a powerful traveling crane.

Crowe Foundry Partly Burned.

A serious fire occurred at Guelph on March 22, when the three-storey varnish and paint shop of the Crowe Iron Foundry was destroyed. The firemen experienced the greatest difficulty in saving the adjoining plant. The molding shop was flooded with water, but otherwise no damage was done to this department. The loss is estimated at $21,000.

Jenckes' Plant Ready.

The new plant of the Jenckes Machine Co., Sherbrooke, is already ready for manufacture and in the boiler shop some operations have commenced. The new buildings include the latest style of steel and concrete structure, two in number, one being designed for boiler manufacture and the other, the foundry. Ample space was left between these two buildings for the erection of the machine shop, which will be undertaken later. In addition to this a handsome brick office building has been erected. This plant when it has received its full equipment of machinery will compare with any in this country. Full installation of machinery is now under way and it is expected to have the plant running full blast at an early date.

Electrical Contractors Organize.

The electrical contractors and supply men of Montreal have reorganized and become incorporated into an electrical section of the Builders' Exchange. The officers for this branch of the exchange were elected as follows: President, E. W. Saver; secretary, J. H. Lauer; committee, F. H. Leonard, R. Moneel, N. W. McLaren, W. J. O'Leary, S. J. Parsons, J. C. Scott.

U. S. Steel Plant in Canada.

The United States Steel Corporation has definitely decided to come into the Canadian market. They will erect their own plant, and land for this purpose has been actually bought. The papers were finally signed this week. Full details will not be made public for some time, for they are not completely worked out.

The New York correspondent of Hardware and Metal states that it may be some time before building operations begin, and the entire plant will not be finished for two or three years or longer. This will depend on the industrial development of the country.

It was stated at a meeting of the directors of the company that about $75,000,000 would be spent on the plant eventually. It is intended, however, to complete certain parts and put them in operation as soon as possible. This will entail an expenditure of $10,000,000.

There are stories, which are no doubt based on facts, that the United States Steel Corporation has acquired extensive ore areas in Ontario. One of these areas, which had been carefully examined, is reported to be the most extensive in the world. The company is said to have some undeveloped coal fields not far from Lake Erie, which will be used to supply coke for its Canadian plant.

Companies Incorporated

The Lloyd-Thompson Wire Company has been incorporated under Ontario charter with a share capital of $75,000 for the purpose of making all kinds of wire. The provisional directors are C. S. Lloyd, G. C. Thompson, and W. M. Smith, with head office at Toronto.

Galt Electric Gas Fixtures Company has been incorporated under Ontario charter with a share capital of $40,000 for the purpose of manufacturing electric and gas fixtures. The provisional directors are Henry Dakin, R. G. Struthers and M. A. Secord, with head office at Galt.

The Montreal & Great Lakes Transportation Company has been organized, with a capital of one hundred thousand dollars. The company will operate a fast and modern fleet of steamers between Montreal and Fort William, Ont., and their business, for the present, will be confined to freight.

The Canadian Northwest Coal Company has been incorporated under Dominion charter with a capital stock of $1,000,000 for the purpose of mining and dealing in coal. The provisional directors are Hon. Robert Watson, C. W. N. Kennedy ,F. C. N. Kennedy. David Philip and E. B. Nixon, with head office at Winnipeg.

The Canada Smelting & Refining Company has been incorporated under Dominion charter with a capital stock of $15,000 for the purpose of manufacturing and smelting all kinds of metals. The provisional directors are G. P. McClure, M. J. O'Brien, T. J. Gates, W. Chagnon and F. H. Wilkinson, with chief place of business at Montreal.

Winn & Holland have been incorporated under Dominion charter with a capital stock of $100,000 to manufacture and deal in iron, steel, machinery and tools. The provisional directors are P. H. Holland, Estelle L. Allien, wife of P. H. Holland, W. J. Michaud, R. A. Holland and G. A. Holland, with chief place of business at Montreal.

The Moffat Fuel Saver Company has been incorporated under Dominion charter with a capital stock of $100,000 for the purpose of manufacturing smoke-consuming and fuel-saving apparatus. The provisional directors are N. J. Ker, J. G. Turiff, E. Seybold, A. Fleck, R. C. Tate, W. H. Ostrom, A. W. Fraser, D'Arcy MacMahon and John Moffat, head office at Montreal.

The Smith Marble & Construction Company has been incorporated under Dominion charter with a capital stock of $40,000 for the purpose of carrying on the business of contractors and builders. The provisional directors are Peter Smith, Allan Smith, D. A. Campbell, W. J. Henderson and A. C. Calder, with with head office at Ottawa.

Dynamic Machine Works has been incorporated under Dominion charter with a capital stock of $15,000 for the purpose of manufacturing electrical apparatus and machines. The provisional directors are S. Humphreys, G. Humphreys, E. J. Featherstonhaugh, Lloyd Blackmore and W. G. Throsby, with chief place of business at Montreal.

The Cobalt Silver & Copper Mining Company has been incorporated under Ontario charter with a share capital of $500,000 for the purpose of carrying on a general mining and development business. The provisional directors are F. E. Ketchum G. P. McCallum, C. W. Baldwin, C. J. Brook and C. H. McBean, with head office at Sault Ste. Marie.

The Canadian Bag Company has been incorporated under Dominion charter with a capital stock of $1,000,000 for the purpose of manufacturing bags, jute, linen, cotton cloth, twines, etc. The provisional directors are H. R. Drummond, H. L. Rutherford, Edgar McDougall, A. W. P. Buchanan, G. L. Cains and J. S. Robertson, with head office in Montreal.

Sanderson Pearcy & Company have been incorporated under Ontario charter with a share capital of $100,000 for the purpose of taking over the Sanderson Pearcy business and continuing it as manufacturers and dealers in paints, colors, etc. The provisional directors are Sanderson Pearcy, C. N. Haldenby and J. D. Craig, with head office at Toronto.

Sheldons Limited has been incorporated under Dominion charter with a capital stock of $200,000 for the purpose of manufacturing and installing heating, ventilating and drying systems and structural steel, etc. The provisional directors are W. D. Sheldon, S. R. Sheldon, J. M. Sheldon, W. H. Sheldon and J. R. Blake, with chief place of business at Galt.

The Dominion Foundry Supply Company has been incorporated under Dominion charter with a capital stock of $50,000 for the purpose of manufacturing and dealing in foundry and machine shop equipments. The provisional directors are D. S. Donald, J. F. Gaffney, G. H. Weaver, E. W. Gilman and E. H. Bennett, with chief place of business at Montreal.

The James Bay Mining Company has been incorporated under Dominion charter with a capital stock of $20,000 for the purpose of carrying on a general mining business. The provisional directors are Adam Burwash, Duncan Lunam, Patrick Gibbons, R. S. Smith, Norman McCuaig and M. J. Malone, with chief place of business at North Temiscamingue, Que.

Hydrogenic Fuel Company of Canada has been incorporated under Dominion charter with a capital stock of $100,000, for the purpose of manufacturing furnaces and apparatus for the combustion of hydrogenic fuel. The provisional directors are J. C. Simpson, P. M. Robertson, S. A. McMurty, F. H. Shaw, and F. G. Bush, with chief place of business at Montreal.

CANADIAN MACHINERY BUYERS' DIRECTORY

To Our Readers—Use this directory when seeking to buy any machinery or power equipment. You will often get information that will save you money.

To Our Advertisers—Send in your name for insertion under the heading of the lines you make or sell.

To Non-Advertisers—A nominal rate of $1 per line a year is charged non-advertisers.

Modern Engines and Power Generators

A Practical Work on Prime Movers and the Transmission of Power: Steam, Electric, Water, and Hot Air. Written for Everyday Use.

For the engineer or machinist who wishes to know the real science of modern power development and transmission, nothing so thoroughly useful as this work has ever been published. It describes and illustrates every existing form of engine and generator, gives the comparative values of fuels, discusses energy from every point of view, describes the various forms of dynamos and motors, and explains in detail, with diagrams and illustrations, the peculiarities of all prime movers in modern use. See Review notice in the March **Machinery.**

Full particulars about this valuable work will be sent free if you will cut out the accompanying coupon, sign, and mail to us. DO IT NOW.

HAVE YOU TRIED OUR WANT COLUMNS?

RATES

One insertion—25c. for 20 words; 1c. a word for each additional word.

Yearly rate—$2.50 for twenty words or less, 10c a word for each additional word.

The above does not apply to notices under the head of "Machinery Wanted." These notices are inserted free for subscribers.

MACHINERY FOR SALE.

FOR $650—Half value—one 10 h.p. engine; one 40 h. p. boiler, 50-ft. stack; 1¾ acres land; good house, mill building and stable; suitable for small factory; or will sell machinery separate; location, Hepworth, Bruce County. Write R. Murdoch, Sault Ste. Marie, Ont,

POSITION WANTED ON COSTS

A YOUNG MAN with several years' experience on time-keeping and figuring of costs in a large manufacturing concern, would like position as cost clerk or shipper with live company; at present with original firm; highest references; state salary. Address J. B. C., c/o CANADIAN MACHINERY, Toronto.

MACHINERY WANTED.

WANTED—Second-hand machinery to completely equip sash and door factory, including boiler and engine; describe condition of machines and give price. F. Wood, Chesterville.

WANTED—17 to 22 ton standard gauge switching locomotive; also standard gauge revolving locomotive crane, with clam shell bucket for unloading coal; both must be in first-class condition; give full specifications and quote prices, The Lakefield Portland Cement Co., Limited. Lakefield, Ont.

BUSINESS CHANCES.

MACHINE SHOP—Established 12 years; lathes, drills, grinders, etc.; patterns for 3, 6, 15 and 25 h.p. gasoline engines; automobile engine patterns for 6. 12 and 16 h.p.; also several other patterns and engines in stock at present; repair trade paying big profits; in Canadian town of 45,000 inhabitants; must be sold at once on account of ill-health of proprietor; price about $3,000. Box 301, CANADIAN MACHINERY, Toronto.

LOCATION WANTED—We are seeking a location for a steel stamping industry that will give employment to about 75 hands; owing to large demand for articles of this kind in Canada, we are desirous of locating there; what inducements can a progressive city offer? Address reply to The Crescent Machinery Co., 1,535 Williamson building Cleveland, Ohio.

INDUCEMENTS SOUGHT—A firm employing over a hundred hands, would like to get full particulars of inducements offered by Canadian towns and cities to branch of reliable and well established concern. Reply to Manufacturer, c/o CANADIAN MACHINERY, Toronto.

FOR SALE at a bargain, Moorefield flax mills; in complete state for operation; possession at once; 200 bushels of flax seed; can be placed out this spring; large buildings, fine boiler and engine, with power to add other machinery, such as planer or chopping mill for which there is fine opening. A. Malcolmson, Secretary, Moorefield, Ont.

AGENTS WANTED.

WANTED—Practical machinists, to act as representatives of CANADIAN MACHINERY in the shops they work in; liberal commission offered. Address Business Manager, CANADIAN MACHINERY.

This page should be one of the most valuable in the paper to all its readers. Do not fail to read every notice. Reply to those that interest you.

Machinery For Sale

Owing to the expiration of our lease, we will vacate our present premises, cor. of St. Catherine and Peel Streets, on or about May 1st, 1906, when we will dispose of

1 50 h.p Horizontal High Speed Laurie Engine, with 10 inch wide driving belt.
1 45 k.w. Dynamo (made by Can. Gen. Electric), complete with marble switchboard (7 switches.)
1 Feed Water Heater.
1 Northey Pump, 3x2x7.
1 Northey Pump, 4½x2¾x4.
1 Hydro Steam Machine for passenger elevator, with 950 feet of rope (only in use two months.)
1 Ceiling Machine for freight elevator.
1 8 h.p. Upright Engine.
1 2½ h.p. Motor, 110 volts d.c.
32 Arc Lamps, 52 volts d.c.

About 60 feet of Shafting, Hangers, 8 Pulleys, and a quantity of 3-inch Belting.

A quantity of 1½ inch Steam Pipes and Valves, including asbestos covering for same.

1 small Hand Parcel Elevator, etc., etc.

The above machinery can be now seen in running order by applying to Mr. Walker on the premises at present occupied by

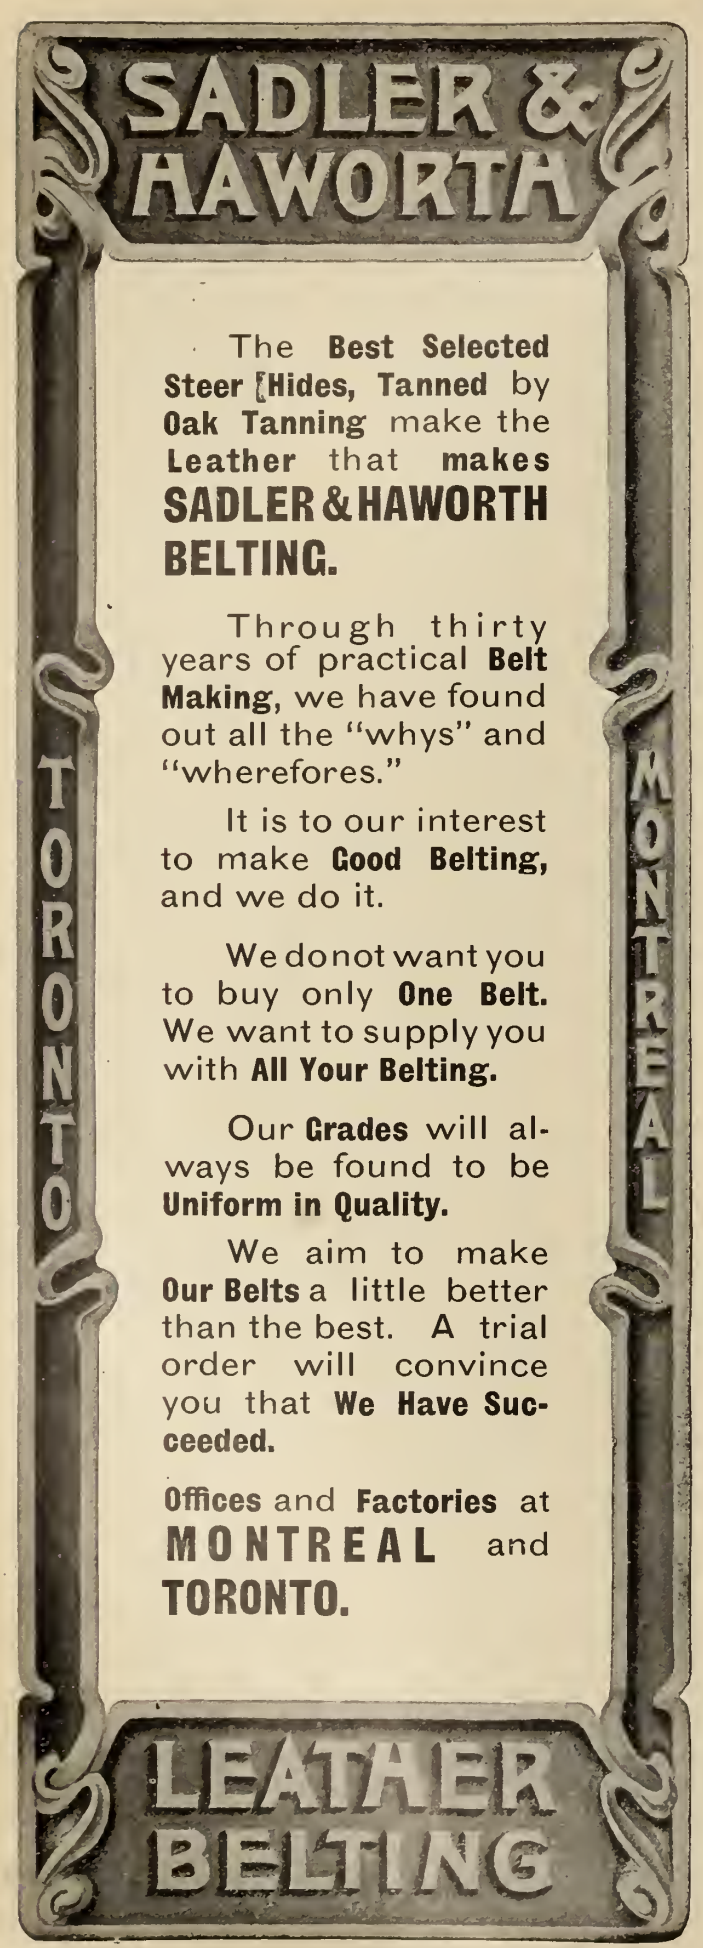
One dollar will bring CANADIAN MACHINERY to you for 12 months. Send the money to-day to MacLean Publishing Co., Limited, 10 Front St. E., Toronto.



SADLER & HAWORTH
The Best Selected Steer Hides, Tanned by Oak Tanning make the Leather that makes SADLER & HAWORTH BELTING.
Through thirty years of practical Belt Making, we have found out all the "whys" and "wherefores."
It is to our interest to make Good Belting, and we do it.
We do not want you to buy only One Belt. We want to supply you with All Your Belting.
Our Grades will always be found to be Uniform in Quality.
We aim to make Our Belts a little better than the best. A trial order will convince you that We Have Succeeded.

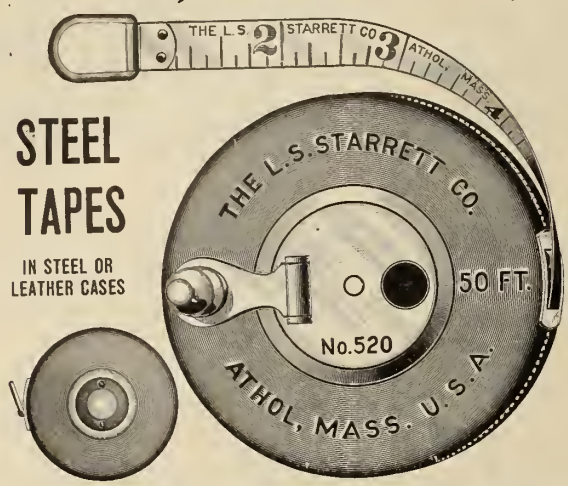
STARRETT TOOLS

ARE THE STANDARD

FOR ACCURACY, WORKMANSHIP, DESIGN AND FINISH



STEEL TAPES

IN STEEL OR LEATHER CASES

In our tapes the figures denoting feet are smaller than those denoting inches. Two reasons for this : .

This dissimilarity of figures materially lessens (in fact ought to entirely prohibit) the liability to erroneous readings that frequently occur through the uniformity of all figures in steel tapes of other makers.

The smaller figures, denoting feet, allow the graduation line under each to be plainly visible, instead of being obliterated by the usual larger figure.

Graduated in feet, inches and eighths of an inch, or in feet, tenths and hundredths of a foot.

3 x 36-inch Pratt & Whitney Turret Lathe, driven 5 h.p. motor.

The motor drives through a speed-box which, with the double friction back-gears, affords a wide range of speeds.

Cross and longitudinal power feeds are positive geared, reversible, and have automatic stops in either direction.

The cross slide permits the use of larger forming tools than can be held in a turret and makes possible the use of three turret tools at one time.

Sylvester Gasoline Engines

Are the best that skilled labor can produce.

They are easy starting; they are simple and reliable; they will give full power in the coldest weather. Made in sizes from 4 to 32 horse power in portable snd stationary and from 1½ to 12 horse power in marine. They will run on gasoline, coal oil or distillates.

The SYLVESTER Engine inspires confidence because it is so simple in construction. It is the cheapest engine to buy because there is nothing to get out of order.

The SYLVESTER Engine is handsome in appearance, substantial in construction, marvelous in simplicity, unequalled for effectiveness and durability.

THE HIGHEST AND MOST PERFECT TYPE OF GASOLINE ENGINE BUILT.

If you require to purchase, write for Catalogue and our 1906 Calendar. We will then send our Travelling Salesman to you

A Post Card Will Do

Have you read the story of Canada's New Lubricating Graphite? This wonderful discovery is a money saver. It prevents hot boxes and pins, groaning cylinders, etc. It reduces oil and grease consumption by one-fourth. It increases the compression of Gas and Gasoline Engines. It remains suspended in oil and will feed through any lubricator. A little does the work. This knowledge means money in your pocket. **A POST CARD WILL FETCH YOU THE STORY AND A SAMPLE PACKAGE. WRITE TO-DAY.**

Vertical Bending Rolls

This machine is built in two sizes, for plates 10 feet wide and 1½ inches thick; 12 feet wide and 1¼ inches thick. The rolls are arranged in pyramid form and the two fixed rolls are positively driven in either direction. The bending roll is adjustable by power and provided with suitable indicator to facilitate the setting. The upper bearing of bending roll is so arranged as to be thrown back to permit the roll being raised clear of the housing for the removal of rings or flues. The gearing is placed beneath the floor and is driven by 50 H.P. reversing motor.

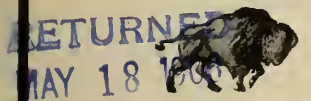
TECHNICAL BOOKS

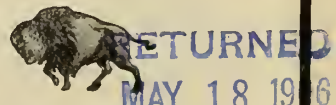
Have you noticed that the owners, managers and superintendents of manufacturing concerns who are constant readers of the best technical works, are the ones who succeed, who get the most out of their plant, their men, their material? It's a fact. Keep in the front rank. Keep posted by reading the best technical books. Get them from

The Technical Book Dept., MacLean Pub. Co., MONTREAL TORONTO WINNIPEG

FACTORY HEATING

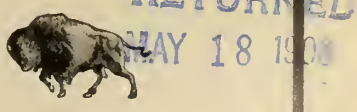
and Ventilation by the Fan System Possesses Inherent Economical and Hygienic Advantages.





It requires one-fifth the radiating surface (expensive piping, coils, radiators, etc.) of the direct system. It occupies no valuable floor space.

Its flexibiiity meets weather changes—Periods of unusual coldness—and provides for future extensions. It means a centrally located plant in charge of one competent man.



No steam Losses. Condensation Returned Direct to Boiler.
Can we interest you further in this System?

The Lever You Want Right At Your Finger-Tips

Stop running "round" to the back of your machine for a lever that you use from 1 to 20 times a day.

Everything Within Easy Reach of the Operator

This is what we claim for this new 30″ **BICKFORD RADIAL**—in fact for all our Radials. And we can prove it, too, not by argument or glib assertion, but by actual demonstration. Look at the cut—did you ever see a handier, neater or more stockily built Radial in your life?

And it's just the thing for taking care of the ordinary work as found in the average shop—it was built for that purpose, you know.

Then, again, we want you to put in the little Radial in place of the large Upright you were thinking of buying. It doesn't cost much more, has infinitely greater productive capacity and will out-last and out-drill any Upright ever built.

It's made in three lengths of arms, remember, 30″, 36″, and 42″.

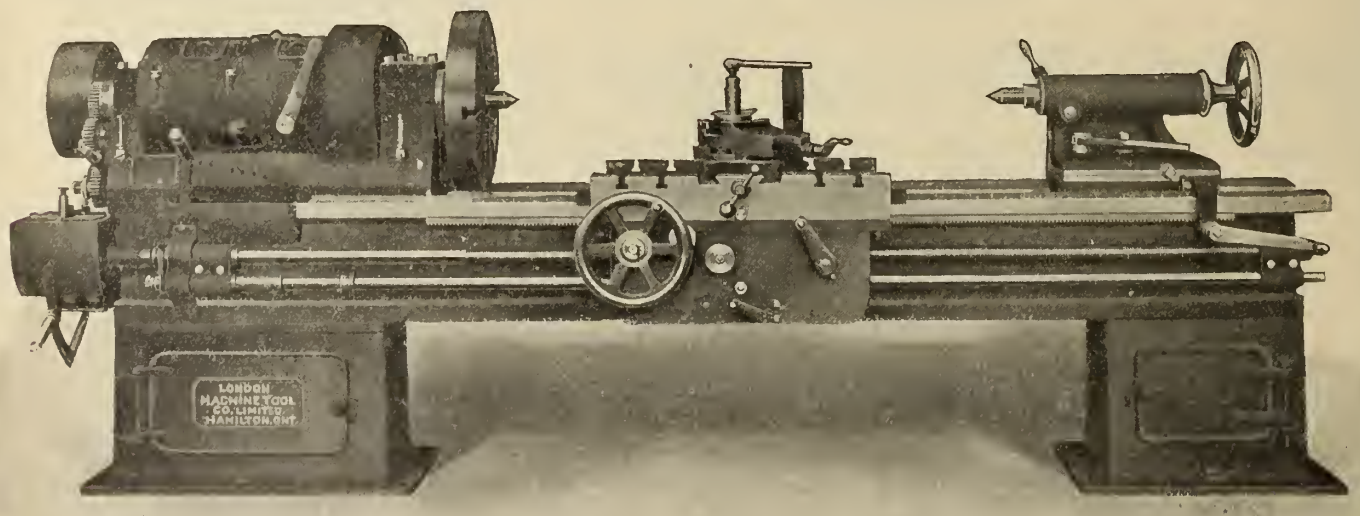
Our New Plant at Hamilton, Ont.



New Type, 22 in. All Geared Lathe.

HAMILTON, - ONTARIO

To the Canadian Machinery Trade:

We beg to announce that we have appointed as our representative for the Dominion of Canada

GEO. H HOWARD, Dundas, Ontario

He will be pleased to place before any prospective customers full information regarding our product. Write him for literature and prices.

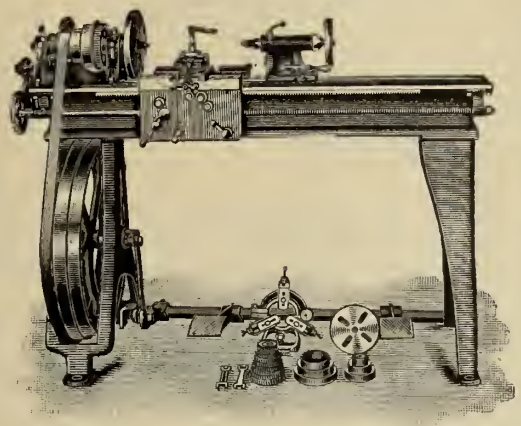
Cleveland Automatic Machine Co.
Cleveland, O.

Potter & Johnston Machine Co.
Pawtucket, R.I.

LOCAL OR LONG DISTANCE PHONE, 65 DUNDAS.

HERE IS THE FINEST LITTLE LATHE IN THE BUSINESS.

ACCURATE



CONVENIENT

Has full compound rest with graduated base, power cross feed, offset tail stock with set-over adjustment for taper work, hollow spindle, and a lot of other useful features found on larger lathes. Cuts right and left hand threads and metric screws when so ordered. Size here shown is our 11-inch screw cutting lathe, furnished in either foot power or countershaft style.

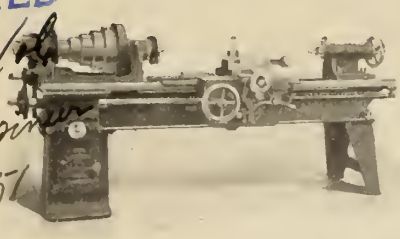
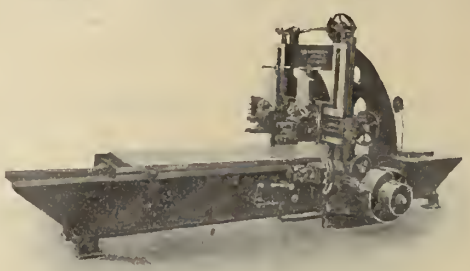
LATHES, PLANERS AND PIPE MACHINES

MADE IN GALT, CANADA



For all purposes, and designed to make good.



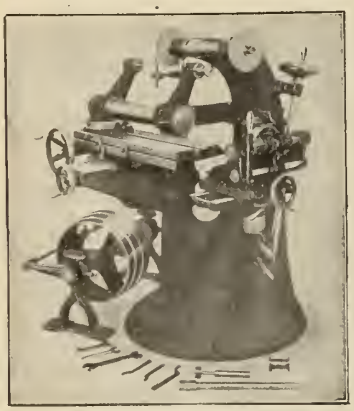
Built like machine tools, and please every time.

Our machines are just a little better than competition demands, but you get the benefit. We are satisfied if the user is pleased.

PARTICULARS YOURS FOR A REQUEST

THE R. McDOUGALL CO. Limited,

GALT ONTARIO CANADA



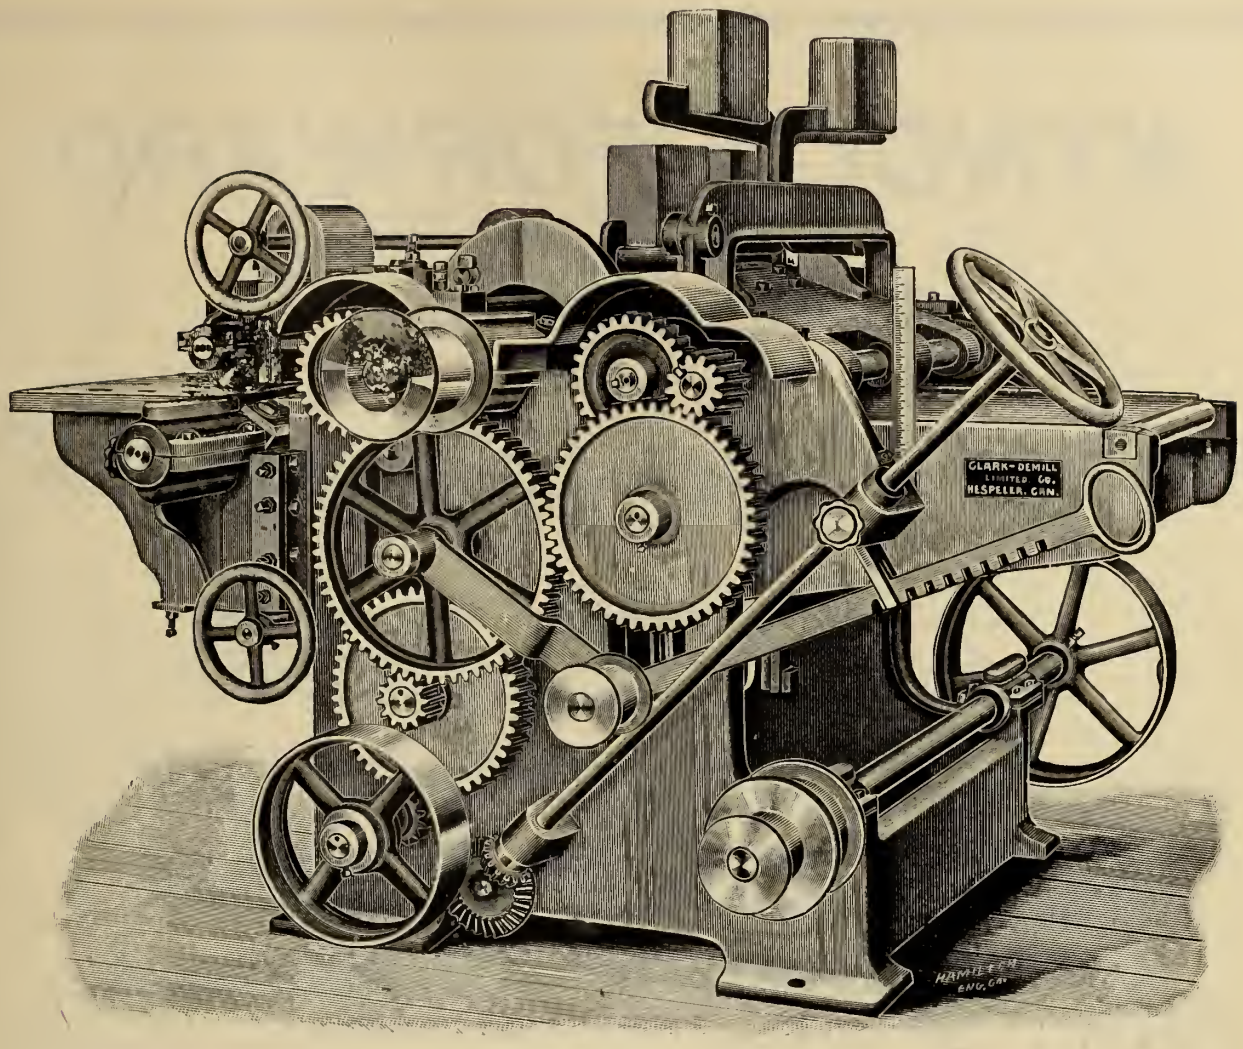
No. 1-14 Cutter and Reamer Grinder.

WE HAVE A FEW OF THESE MACHINES READY FOR IMMEDIATE DELIVERY

This machine is distinctly a cutter grinder, and was designed to fill the want for a machine to sharpen milling cutters of all kinds and shapes, without special fixtures or special-shape emery wheels, being heavy enough to eliminate all vibration and still be easily operated. It weighs about 1370 lbs. The table, which has a long bearing on the saddle, has a longitudinal feed of 20 in., cross adjustment of 7 in., with a vertical adjustment of 6 in. Cutters 1 in. to 14 in. can be taken between centres. The table can be used at different angles with the spindle in horizontal plane, by swiveling the knee around the column. The machine is compact, durable, adaptable and a necessity for the busy shop.

Becker-Brainard Milling Machine Co.

HYDE PARK, MASS.



Our No. 118 Double Surface Planer, 26 in. x 10 in. thick. Plain or divided Roll. Why spend time handling your material twice when you can have it surfaced two sides with one handling? Do you know what it is costing you to handle your material so often? Sit down and figure it up and you will find that it will pay you to buy a machine that surfaces your stock on both sides with one operation.

If this machine is not heavy enough for you, why, we make heavier, and will be pleased to tell you about them.

All work guaranteed to be of the highest order.

CLARK-DEMILL COMPANY, LIMITED, Hespeler, Ontario, Canada

Modern Canadian Manufacturing Plants.

ARTICLE XV.—New Foundry, John Bertram & Sons, Limited, Dundas, Ont.

WHEN the general public had been made cognizant of the fact that additional strength and larger interests had become associated with the firm of John Bertram & Sons, Limited, Dundas, plans were already well under way for extensive additions to the works part of which are exemplified in the new foundry. This building is but part of a general scheme, the main features of which have already been planned by the engineers of the firm, and which when carried out in full will make the Bertram works one of the largest manufacturing concerns in the Dominion. Less than a year ago the spot where the foundry is now situated was occupied by a beautiful residence with attractive grounds surrounded by a magnificent row of maples.

Manufacturing demands cannot consider the aesthetic, however, and these have disappeared to give way to a hive of industry, making employment for a larger number of men than were formerly needed, increasing the town's population, adding to land values and becoming a point of material production.

The location of this building is at considerable distance from the present machine shops, making ample allowance for their extension. Everything about it, both in its construction and equipment, is the latest and best that modern materials and methods could suggest, so that while there are many larger foundry buildings there is probably not one superior on the American continent. The material used both for the structural work and for the inside arrangement and devices is in all instances, where at all possible, of Canadian origin.

New Foundry, John Bertram & Sons, Limited, Dundas.—East Wing, Looking North.

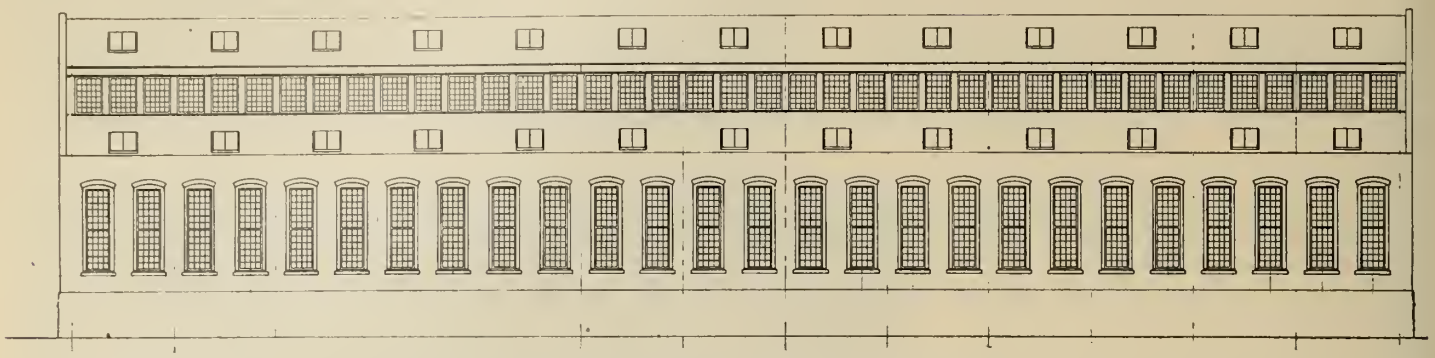
The Foundry Building.

Situated at the northeast corner of the block of land containing the Bertram premises, the foundry is probably the most easy of access for outside transportation of any of the buildings in the works. The structure itself is of brick on concrete foundations, which extend downwards of sufficient depth to give ample depth allowance for the molding floors. The frame work is of steel, furnished by the Phoenix Bridge Works, of Montreal. Work was commenced on Oct. 1, the contract being in the hands of Haney & Miller, of Toronto, and owing to the comparatively open Winter excelent progress was made, so that now the building is fully completed and ready to carry on extensive operations. The size of the building is 210 feet by 109 feet inside measurement, and is, as will be seen from the illustration showing the end views, divided into three sections or bays. The main central section being 52 feet in width to allow 50 feet clear span for crane, which latter is situated 20 feet 3 inches from the floor. The eastern bay is of one storey, 28 feet 9 inches in width and 10 feet 9 inches under the crane, while the western bay is approximately the same width, but is of two storeys containing a gallery 10 feet high, the floor of which is 20 feet 7 1-2 inches above the main floor. The roof trussed structure is also shown in this view while this and the side view given show the ample allowance that has been made for lighting

New Foundry, John Bertram & Sons, Limited, Dundas.—Main Bay, Showing Cupola Room to Right.

space. The brick used in the construction is from the Port Credit plant.

The door frames are of cast iron and the window sills cement reinforced. The glass in the skylight is reinforced by wire and the entire building has practically no combustible material except a layer of planking in the roof, which is well protected from the outside by fireproof material.

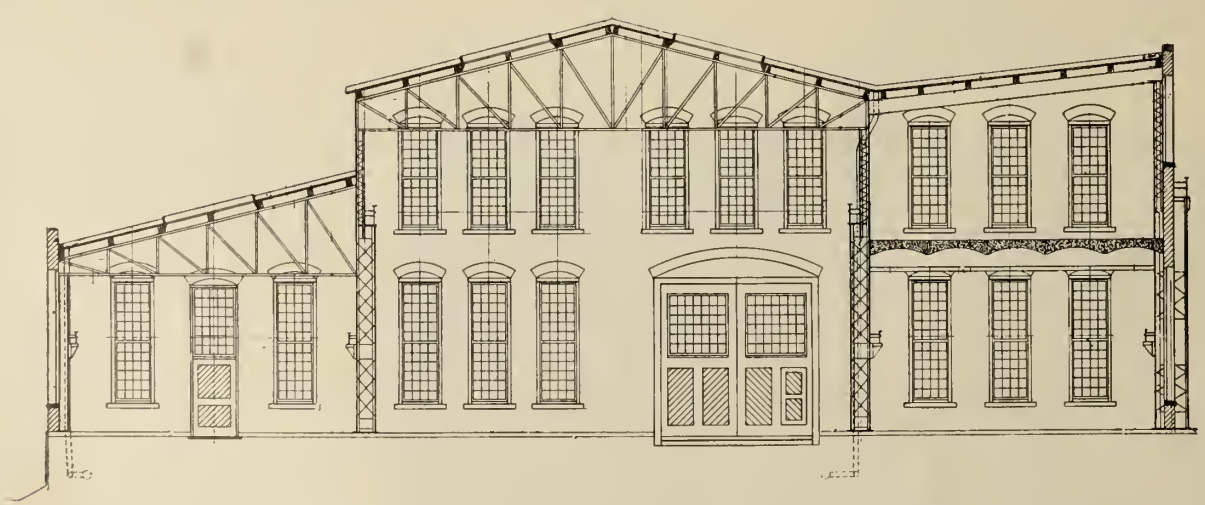


New Foundry, John Bertram & Sons, Limited—East Side Elevation.

Inside Arrangement.

The general scheme as devised and carried out has the end in view of the greatest economy in manufacture, and the latest practice known to the foundrymen both in materials and devices have been adopted. In the arrangement of the departments it has been so planned as to have the most harmonious connection between them to promote expeditious and at the same time high-class work. The floor is composed of 6 feet of sand, having been filled in specially, as is apparent, a very large amount of special sand being necessary to supply this. This gives ample depth for the largest floor castings that may be required. A minimum of hand labor is one of the points that have been kept in mind in this arrangement. The different departments include the east wing, which along its entire length is devoted to floor moldings, as well as the main centre bay for the same purpose, while the west aisle besides containing the gallery above, includes the core room with the large ovens, the cupolas as well as a molding floor, where will be situated the molding machines and where snap work will be done.

The cupola room is situated near the middle of the west wing and is brick walled from the rest of the building. In this has been placed two cupolas. The room is 22 x 29 feet, giving ample room for the operations required. The large cupola is 60 inches in diameter inside lining, and a smaller one 40 inches, both fitted with spark arresters, the blast being furnished by Root No. 6 blower. Here are also situated the tumbling barrels, in which the furnace bottoms are cleaned whence the scrap iron is returned to the charging floor to be remelted. A large elevator connects this room with the gallery floor. This may be loaded directly from the cars and the pig iron landed on the charging floor above with a minimum of effort. On the opposite side of this room is a sand and coke elevator, manufactured by the Waterous Engine Works Co., Brantford, which can also be fed from outside, by means of which the sand and coke are carried to the gallery floor. The blower mentioned above is directly connected to a Westinghouse 40 H.P. induction motor, the same blower serving both cupolas. The conveyor, elevator, tumbling barrels and sand-coke conveyor on the gallery floor are all operated by individual motors.



New Foundry, John Bertram & Sons, Limited—End View Showing Steel Structure.

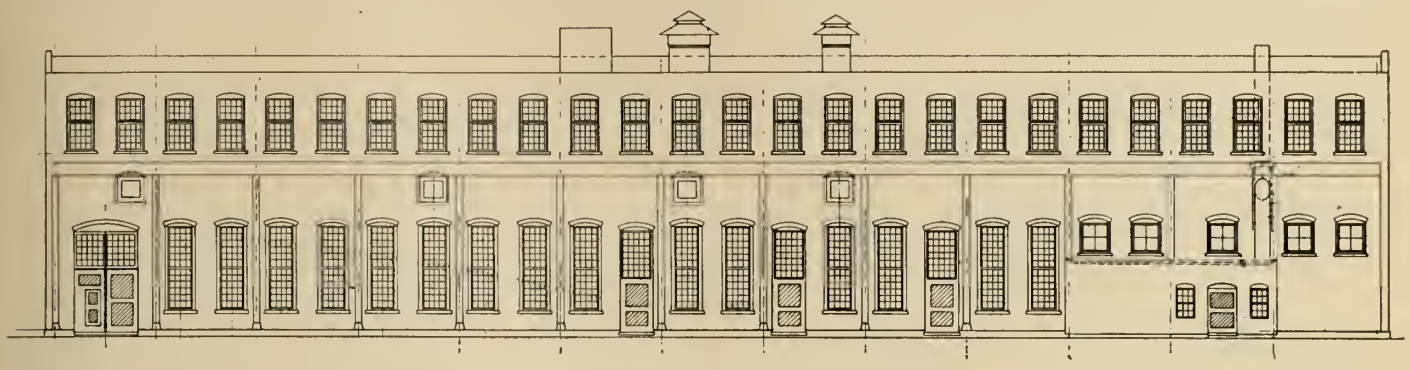
Core Room.

In this department a space of 70 feet by 28 feet 3 inches is reserved, the entire floor being covered by a 5-ton Niles traveling crane and in the rear of which are situated the core ovens. Two of these are 30 x 14 feet and another 12 x 20 feet, all brick lined in cement. All three ovens are fired from one central furnace by coke, but it is proposed to utilize natural gas, which has been available in Dundas for about a year at 30 cents a thousand.

Gallery Floor.

This feature of the building is probably one of the most important in connection with the plant inasmuch as it

embraces a large number of features that go towards economy of production and the lessening of labor. The floor of this gallery is of concrete, the detail of which is shown in the end view of the building, and the roof structure immediately over the cupolas and for some distance on each side is of the same material. This comprises the charging floor for the cupolas as well as the store room for sand and castings. Connecting with the sand and coke elevator from below an endless conveyor whose scope extends to the south end of the building. The coke is deposited from the elevator in a large wire bin situated near the charging doors of the cupolas, so that practically no distance is required to be covered on the part of the operator in charging. The sand conveyor conveys the sand to as many different stations as may be required, the dumping being accomplished by means of sliding doors situated on the floor of the conveyor. Here the sand is treated, whence it is shovelled through circular trap doors which lead to the different molding floors where the sand is required. A view shows the general lay-out of this floor and the situation of the apparatus just described. The mixing of the sand on this floor by means of power sand mixers and its conveyance by shutes to the different sections of the foundry is a great economy, as when the sand is mixed on the molding floor it is extremely difficult to convey.

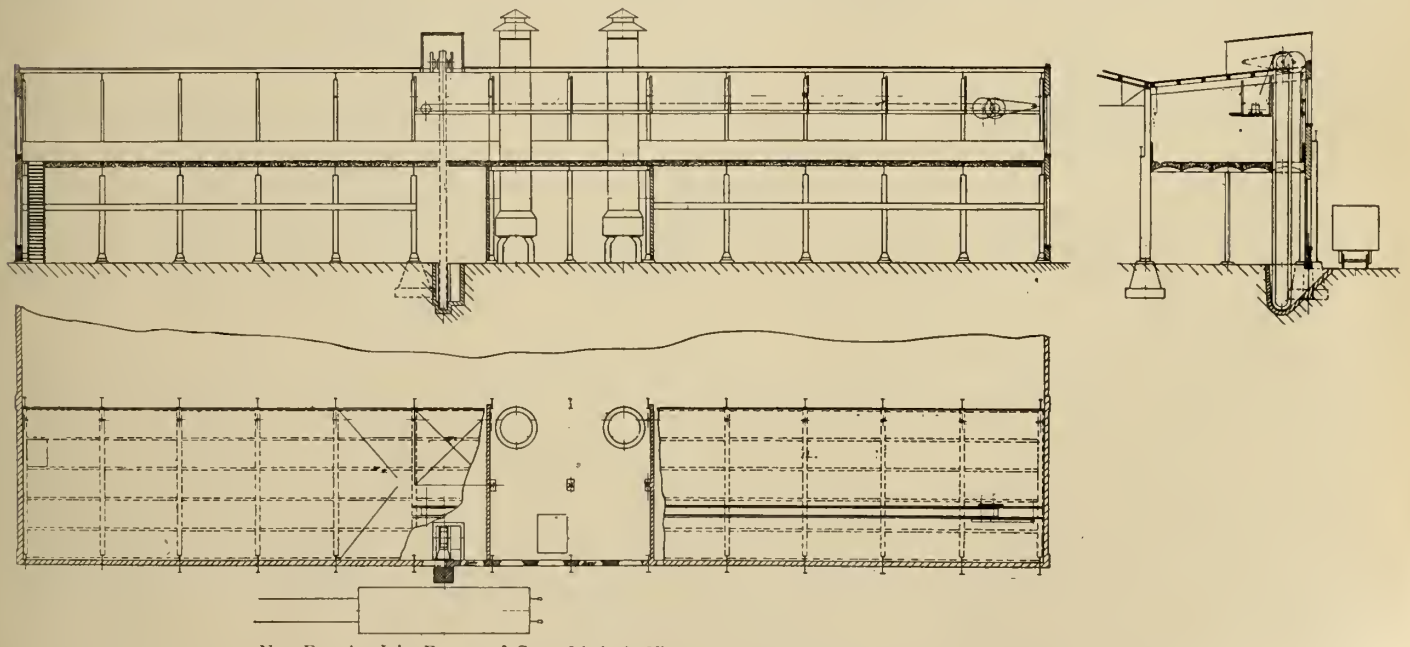


New Foundry, John Bertram & Sons, Limited—West Side Elevation.

Transportation Facilities.

A plan of the building and nearby grounds shows the general track arrangement by means of which cars may bring their raw material alongside the foundry and convey it directly to the elevators already mentioned, or makes possible bringing a car into the centre aisle of the building where material may be loaded directly by means of the large crane. In the building itself the different departments are served by traveling cranes, the east bay being covered by two of 5-ton capacity and the centre bay by a 25-ton crane fitted with a 5-ton auxiliary hoist. The steel girders for these were furnished by the Phoenix Bridge Works. In addition to this, for the middle bay, an auxiliary 10-ton crane is to be installed. In the west side a 5-ton crane conveys the material to and from the different parts of this department. Besides these labor-saving devices a yard crane is to be installed with a 60 foot span for the economic handling of outdoor materials.

In addition to the equipment already mentioned a complete air compressor plant is being installed. This is to be operated for chipping and cleaning patterns, running air hoists, blowing molds, pneumatic sand shakers and pneumatic molding machines, of which an up-to-date equipment is being installed. Each floor is furnished with water service and hose for wetting down the sand before tamping. The comfort of the men has been considered in the heating, ventilating, lighting and lavatory installations. The heating is accomplished by direct radiation, the system of coils being placed next the outside walls and on the column of the centre bay thus form-

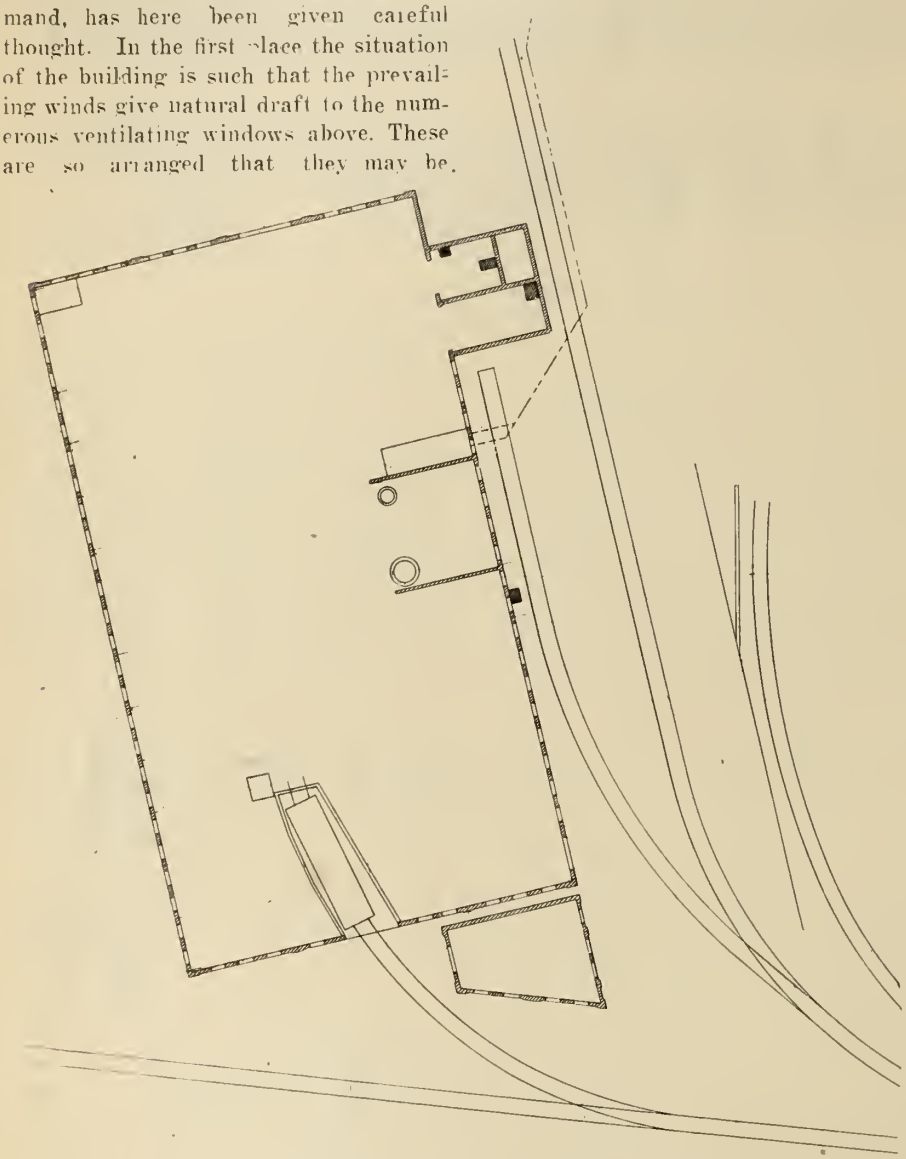


New Foundry, John Bertram & Sons, Limited—Views of Cupola Room and Gallery Floor Showing Elevators.

ing partitions between the departments and providing places which may be used as storage room for materials in every day use. A temporary boiler at present supplies the heat required, but later this building as well as the works will be heated from a central heating station.

The ventilation, which is such an important feature in the foundry building and which so often receives less consideration than the circumstances demand, has here been given careful thought. In the first place the situation of the building is such that the prevailing winds give natural draft to the numerous ventilating windows above. These are so arranged that they may be operated independently. The apparatus in connection with the operations of these is furnished by the King Construction Co., Georgetown. On the west bay the window sashes are made to swing on pivots, and these likewise may be opened independently or in groups.

The lighting of the foundry is another serious problem, but which seems to have been settled in a most admirable manner in this case. The exterior views will give some idea of the excellent lighting facilities afforded by natural means, but this is supplemented on a large scale by artificial light. It was finally decided to use Nernst lamps for this purpose, this being the first installation, on a large scale, of these in a factory equipment in Canada, but their utility has already been demonstrated in large industrial concerns in the United States. About 42 in all will be required and during the days when artificial light is needed in the morning and in the evening, will supply the workmen with all the light necessary.



New Foundry, John Bertram & Sons, Limited—Plan Showing Railway Switches.

Transformer House.

The whole plant is to be electrically driven from a central transformer station, shown in the plan at the north end of the foundry. The building itself is essentially fireproof, being constructed of concrete and brick, with fireproof roof. It is being installed with a capacity of 400 K.W., the power being supplied by the Cataract Power Co., Hamilton. In addition to the kilowatt capacity mentioned, an additional set of transformers will prevent any accident stopping the works for want of power. A 175 K.W. motor generator set, manufactured by the Canadian General Electric Co., will supply the direct current for the cranes. A 75 H.P. motor will run a Canadian Rand drill air compressor, and a 1,000 gallon, electrically driven fire pump will supply pressure for the water mains. A large panel switchboard takes care of the incoming lines and the distribution of the electrical energy to the different parts of the plant.

PERSONAL MENTION.

Mr. E. R. Clark, hydraulic engineer, has severed his connection with the Canada Foundry Co., to go into business for himself, having become associated with Connor, Clarke & Monds, consulting engineers, 36 Toronto street, Toronto.

Mr. R. A. Wallace, for the past four years superintendent for the Hamilton Gas Co. works, has resigned his position and will leave shortly to accept a very important position at Quebec, that of superintendent and engineer of the Quebec Gas Co. Mr. Wallace has been connected with the Hamilton Gas Works since he was a boy, and has worked up step by step until he reached the highest position in the company's services.

The delegates who have been appointed to represent the Toronto Board of Trade at the 6th congress of Chambers of Commerce of the Empire, to be held at London, Eng., on July 8, are Messrs. A. E. Kemp, M.P., W. F. Cockshutt, M.P., J. W. Woods, J. F. Ellis, J. D. Allan, D. R. Wilkie, W. J. Gage, R. J. Christie, Noel Marshall, C. W. Band, J. D. Ivey, C. W. I. Woodland, Lieut.-Colonel G. T. Denison and F. G. Morley.

Election of T. P. A. Officers.

At the second annual meeting and banquet of the Technical Publicity Association, held Thursday, April 5, at the Aldine Association, New York, the following officers were elected: President, F. H. Gale, General Electric Co.; 1st vice-president, H. M. Cleaver, Niles-Bement-Pond Co.; 2nd vice-president, C. B. Morse, Ingersoll-Rand Co.; secretary, Rodman Gilder, Crocker-Wheeler Co.; treasurer, H. M. Davis, Sprague Electric Co.; members of executive committee, Robt. L. Winkley, Pope Mfg. Co., and G. M. Basford, American Locomotive Works; members election committee, C. W. Beaver, Yale & Towne Mfg. Co.; Chas. N. Manfred, Johns-Manville Co., and H. H. Kress, A. S. Cameron Steam Pump Works.

Construction and Improvement

General Construction *Contractors' Supplies*

HEATING AND VENTILATION OF FACTORIES.

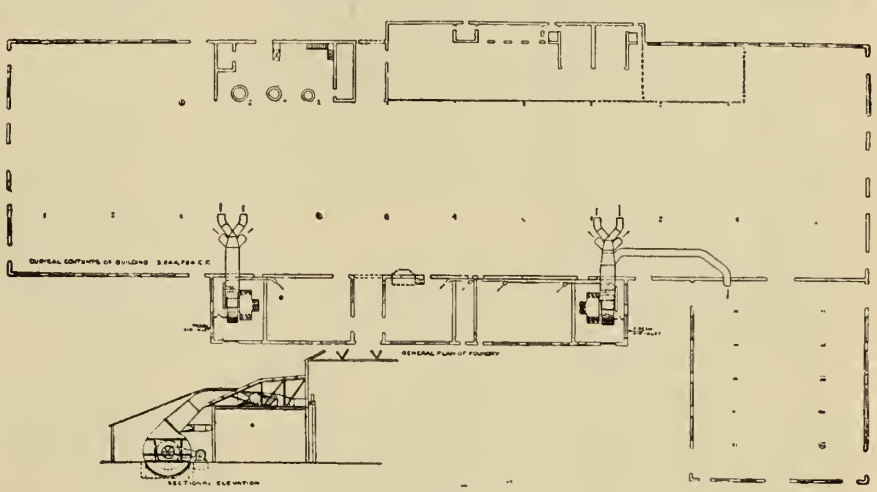
METHODS adopted for supplying and distributing the air in buildings are worthy of considerable attention. The usual methods of supplying heated air are : first, to take the air entirely from without doors and force it directly into the building through distributing ducts. This method is generally known as the plenum system. The pressure produced in the building causes a continuous exit of air from the building, either through the natural openings, as is usually the case in factory and other large buildings, or through special vent openings provided for the purpose, as in public buildings. This effectually prevents the entrance of cold air from without.

A second, and more common method for shop buildings where forced ventilation is not a necessity, is to draw the supply of air entirely from within the building and again force it through the distributing ducts, causing a continuous circulation of the air within the building. This often has an advantage over the plenum system in that all the heat supplied to the air is effective in heating the building.

Some Adaptations.

The ideal system is a combination of the plenum and return systems. This should be used wherever possible. In this system the greater portion of the air is returned to the apparatus, but sufficient air is continuously taken from without through a fresh air connection to create a plenum within the building and prevent the inward leakage of the cold air along the floor.

Excellent results can be secured by the use of overhead piping, providing it is not placed at too great distance from the floor. The chief advantage of the overhead system is the saving in first cost, since, on account of the high temperature and velocity of air in the distributing pipes, a great amount of heat can be transferred with a very small amount of material. The cost of the galvanized iron distributing system of air ducts is relatively small. The best results are secured with outlets at from 12 to 18 feet above the floor line. Above this height it is preferable to use drop pipes extending downward along the columns where they will not interfere with traveling cranes. Such an arrangement of overhead piping is frequently employed in foundries, while in large machine shops underground ducts are nearly always preferable. Another system which has proved very satisfactory is that in which a distributing air return duct is employed. This approaches very closely in principle to the plenum system used in public buildings, and is a combination of both plenum and exhaust systems. The peculiar feature in this is that no distributing ducts or piping for the heated air are used. The air is blown at a comparatively high velocity directly into the building at about 8 or 10 feet above the floor through an outlet branching in three directions, and through which the air passes at a comparatively high velocity. The distribution is effected entirely by the return vent ducts which are placed at frequent intervals along the walls. These open into large return air channels which are provided on either side of the building and serve the additional purpose of affording a convenient place for locating steam and water mains, and also electric light and power mains. Provision is made for taking a portion of the air from without doors to secure a plenum. One great advantage of this plan is that it removes all cold air leaking into the building at the floor line, and that produced by the cold down draft next to the walls, as well. A perfect distribution is secured in all parts of the building, and the cost of installation is reduced to a minimum. In small buildings a system of distributing outlets is placed along the further side of the building, and a system of vent ducts opening into exhaust chamber is placed on the side adjacent to the fan. In many instances an elaborate distribution is impracticable or undesirable. In such cases a centrally located discharge pipe may be used. From this point the air is blown in all directions and a circulation is produced by an exhaust connection to the fan inlet. In such instances very effective heating has been secured even where it was required to blow the air long distances. A good example of such a system may be found in the foundry building of the General Electric Company at Schenectady. This foundry, which is probably one of the largest in the world, is heated in an entirely satisfactory manner with a few large branch outlets.



Type of Foundry Heating Apparatus with Small Amount of Distributing Pipe.

The chief points of excellence of the fan system may be summarized as follows : 1—Perfect ventilation, regardless of exterior conditions. 2—Uniform and proper distribution of heat. 3—High efficiency of heating surface, (three to five times that of direct radiation). 4—Greatest economy in operation. 5—Utilization of exhaust steam. 6—Prevention of cold drafts from without by production of a plenum. 7—Independent regulation of heating and ventilating effects. 8—Central location of plant, requiring a minimum amount of attention. 9—Great flexibility in operation to suit varying conditions. 10—Low cost of installation.

A man may have enough of the world to sink him, but he can never have enough to satisfy him.—T. Brooks.

WE WANT CHEAP POWER.

SUCH was the slogan of the monster delegation that waited on Premier Whitney of Ontario and his cabinet on Wednesday, April 11, where representatives of the various municipalities urged upon the Government the immediate necessity of prompt action to secure and place at their disposal power generated from the Canadian Niagara Falls. This delegation was without doubt the most important and influential that has ever waited upon the Ontario Government. The question is a vital one, in fact no more important problem has heretofore confronted manufacturers of Ontario than the question now under discussion. The two reports, that of the Municipal Power Commission and the Ontario Hydro-Electric Power Commission, have been published and the figures contained in them have caused no small excitement in Ontario municipalities.

As these reports are based upon figures supplied by engineers of repute and have been made after months of investigation on the part of those delegated to take up the work, they must be given attention and held worthy of consideration on the part of all interested. The figures quoted in these show conclusively and undeniably the advantage that would accrue to manufacturing interests, and through them to the whole country, if power were available at the different centres at the prices quoted. One thing that has been brought out in a definite manner and which has caused many people to open their eyes in amazement is the fact of what a valuable asset our water-powers are and what a boon to the country it would be if power from these were supplied at a trifle over the cost of generating.

The Government has as yet in no way committed itself on the question as to whether it will assume control over the power developed or in what way it will endeavor to have it delivered throughout the country. The problem before it is a momentous one, but one that in the face of what has already been done and in view of public opinion in the matter must be dealt with immediately. Those who have invested their money in and shown enterprise in developing the power on the Canadian side deserve consideration, but what the Government must do is to see that Ontario gets the benefit of Niagara's power and that manufacturers are supplied with it at reasonable rates.

CANADIAN CATALOGUES WANTED

CANADIAN manufacturers seeking to extend their trade in Australia, or establish a connection with this sister colony, will be interested in the report of Mr. D. H. Ross, Canadian Commercial Agent for Australia. Some months ago the Department of Trade and Commerce invited manufacturers to supply the various Canadian Commercial Agents with catalogues, export price lists and discount sheets, and the invitation, it appears, did not meet with a general response. The sole object in view was to benefit manufacturers in this country by giving the commercial agents a thorough understanding of the lines produced.

Mr. Ross says there is no doubt the object in view is to give the agent such a firm grasp of the manufacturing advance made by Canada as that he shall, without delay or difficulty, be in a position to advise any local merchants as to Canadian sources of supply and conditions of delivery. Canadian manufacturers or exporters must forthwith disabuse their minds of any suspicion of the idea that the commercial agents would show undue preference to one manufacturer over another. For the commercial agent's influence, as a whole, is employed on behalf of all Canadian exporters, and can take no cognizance of individual or associated speculation. It is well worth some sacrifice of a commercial agent's time and convenience to satisfy on the spot intending importers anxiously seeking information regarding Canadian goods, when the question of over 10,000 miles between Canadian manufacturing centres and Australia precludes intending buyers sending for price lists and obtaining quotations in time for a season's or urgent requirements. The question of having quotations in sterling (£ s. d) is not essential, as importers are accustomed to purchasing goods from United States price lists. Canadian firms already represented in Australia should inform the commercial agents of the names and addresses of their representatives, so when occasion arises the latter may be referred to.

ITALY AS A MARKET FOR CANADIAN PRODUCTS.

FEW people in Canada realize what a change has come over Italy in the last few years. Most of us know that country from our ancient histories and from the hard working, but ignorant and excitable navvies who build our railways and work on our big contracts.

Some time ago Marquis Doria was sent to Canada to see whether trade between this country and Italy could

not be developed. During the last few weeks the marquis has seen many Canadians—leading representatives of the political and commercial life of the country—and has opened our eyes to the possibilities for a really valuable exchange of products and has suggested the advisability of the encouragement of a direct steamship line between Mediterranean ports and Canada. It would open a most valuable part of Europe for Canadian trade. Such a line would be of much more importance to Canada than even our Australian, Mexican or South African routes, because we could place our farm products and many of our manufactures in a short time right among an immense consuming population. Such a line would open a market for Canadian shippers and importers, a district not now touched by Canada at all, Southern France, Switzerland, Northern Italy and Austria, and all these countries are just beginning to take an interest in Canada.

If Canada is to take advantage of trade opportunities with Italy and other countries on the Mediterranean, it is imperatively necessary that a line of steamers should run regularly between this country and ports on that sea.

Italy is a country which, while producing a great many things that this country requires, is also a large importing country. She imports about $12,000,000 worth of machinery, to say nothing of about 5,000 tons of agricultural implements, from plows to reapers. The imports of lumber aggregate about $13,000,000 ; of coal, 5,000,000 tons ; of wood pulp, 30,000 tons. Another Canadian industry which would be benefited by a direct line would be the wheat industry. Italy imports on an average of about 30,000,000 bushels per annum. Last year she imported over 40,000,000 bushels.

MORE CHEMISTRY FOR THE FOUNDRY.

IN his talk on "Foundry Chemistry" at the annual meeting of the Society of Chemical Industry, Mr. H. L. Bowers emphasized the necessity of more scientific methods being adopted in the foundry. The present practice of grading iron by fracture is unreliable and not in accordance with modern methods. A chemical analysis is necessary and until this is adopted, not only by larger firms where such is already the case, but by smaller foundries, there is sure to be dissatisfaction. Even the sand should be analyzed, as its proper constituents mean the difference between good and bad castings. When the chemist is given a berth in the foundry or when the aspirant for the position of foundry foreman is able to undertake chemical analyses, more can be hoped for from that department and fewer instances will be recorded of the foundry running at a loss, as has been too commonly the case in the past.

READERS MISS OFFERED OPPORTUNITY.

AN incident arose the other day which serves to illustrate a point we have desired to make for some time. Among others a subscriber in Guelph wrote to Allis-Chalmers-Bullock, Limited, asking them to forward copies of the dainty little desk calendar which they are getting out from month to month. In referring to the incident the firm mentioned expressed the view that not only were they ready to do the little favor asked but they appreciated the inquiries and would like every firm who had not received a copy to send for it.

We would like every reader of Canadian Machinery to understand this attitude, which is probably true of every advertiser in the paper. The advertiser desires to get into touch with every buyer of his lines. The subscriber wants to learn as much as he can about the most up-to-date machinery, power equipment, etc. The most logical way for these two classes to get together is for the subscriber to read the advertisements, the catalogue reviews, the references in the reading columns to new apparatus, and when anything interests him, to write for it. Write for all literature you see referred to in Canadian Machinery. The advertiser will appreciate such inquiries and you will get information of real value to you.

TELEPHONES FOR ALL.

A TELEPHONE monopoly has had much to do with making the telephone of less universal service than it should be and in view of its utility much less than what might well be expected of it. A bill presented by Hon. Adam Beck before the Ontario Legislature is worthy of commendation, providing, as it does, that municipal councils may organize a telephone system if a group of twenty citizens wish it, and that the municipality petitioning for such a system and showing a plan of the proposed line may set to work on its installation, the cost of the line being defrayed by subscribers. Furthermore, it provides that with the consent of the postmaster-general the switchboard may be located in the local post office. This should give a boom to the telephone in rural districts and should hasten the day when every farmer in the land is connected to his neighbors and the outside world by telephonic communication.

USELESS ENERGY FOR TECHNICAL STUDENTS.

LACK of co-operation between its different departments has often led to the downfall of a promising concern and this very cause is every day working towards an impairment of profits in industrial establishments. In the rush to turn out a maximum output, systematic methods may be overlooked with disastrous results.

There may be some cause for this in the turmoil and activity of an overworked factory, but in a seat of learning where we expect to find the embodiment of quiet, thoughtful, systematic harmony, there is no excuse whatever. A flagrant breach of this principle has just come to light in the science department—of all places the most unexpected—of one of our universities, in which the students have been the sufferers and where gross mismanagement on the part of those in charge has been displayed. In the science course the lectures are supplemented by practical work in the laboratories, where the budding engineer is shown the how of the why and the wherefore given in the subject matter of the lectures he attends. This is particularly true of the subjects dealing with the actual practice of the engineering profession. The professor elucidates the theory and the demonstrator follows up with its application to actual practice. Imagine, if you can, anything more incongruous than these two carrying on their work on independent lines and in ignorance of the other's line of treatment. Yet this is absolutely going on.

As a concrete example, a demonstrator in electrical engineering has been taking up work weeks before it was touched upon by the lecturer, passing over work then being discussed in the class room. For instance, during the term just past he had his students working on the design of a 100 k.w. transformer before they were well launched, in the lecture room, upon the elements of magnetism. In the interests of technical education and for the conservation of energy this should not be the case, but a little more common sense applied where it is supposed to be found in abundance, but where, alas, it is sometimes sorely lacking.

Electric Power for Ontario

MATTERS of the most vital importance to the manufacturers of Ontario have been taking place within the past few weeks. The report of the commission appointed by several municipalities of Ontario to inquire into the cost of developing the power at Niagara, has been handed in, the report of the Hydro-Electric Power Commission appointed by the Ontario Government has been submitted, and the most influential delegation representing all the important municipalities of Western Ontario has waited upon the Ontario Government, urging immediate and definite action on the part of the legislators towards securing power at reasonable rates for the manufacturing industries of the western peninsula.

RETURNED
APR 26 1906

The Hon. Adam Beck,
Whose work has aroused the interest of every Ontario manufacturer.

The Municipal Power Commission, under the chairmanship of Mr. E. W. B. Snider, of Waterloo, which was appointed by the cities of Toronto, London, Brantford, Stratford, Woodstock, Ingersoll and Guelph, recommended the establishment of a municipal power station at Niagara Falls. Included with this was a most exhaustive report made by Messrs. Ross and Holgate, hydraulic and electrical engineers, of Montreal, coupled with a report of Prof. R. A. Fessenden, of New York, and upon these the commissioners' conclusions are largely based. In the event of other municipalities being unwilling to take up the matter it was recommended that the municipalities named carry out with all possible expedition a development of 60,000 h.p. The rates showing the enormous difference between the price it would be possible to supply power to manufacturers if this recommendation were entered into, and the cost that manufacturers are at present obliged to meet in the production of power, were shown.

Cost of Power and Light.

The variations of price required to meet the varying duration of service demanded by consumers must be settled by the operating commissioners with regard to the local conditions of demands, etc. These will vary in each municipality, and, as they will remain unknown until the supply contracts are entered into, they cannot be intelligently approximated.

I. Motor service per h.p. per annum, 24-hour service at consumers' premises :

	30,000 h.p.	60,000 h.p.	100,000 h.p.
Toronto	$21.97	$15.73	$14.60
London	.115	.0925	.0389
Brantford	30.02	17.93	15.57
Guelph	27.68	18.26	16.70
Stratford	33.67	21.45	19.42
Woodstock	34.48	21.05	17.53
Ingersoll	33.96	21.61	17.99

II. Are lighting, cost per lamp per year :

	30,000 h.p.	60,000 h.p.	100,000 h.p.
Toronto	$42.02	$37.61	$36.48
London	54.08	44.89	41.36
Brantford	49.73	42.91	40.55
Guelph	47.84	40.69	39.13
Stratford	56.83	47.23	45.20
Woodstock	56.16	48.16	44 64
Ingersoll	72.58	64.02	60.40

III. Incandescent lighting, cost per k.w.h.:

	30,000 h.p.	60,000 h.p.	100,000 h.p.
Toronto	$.0741	$.0640	$.0614
London	115	.0925	.0839
Brantford	.0945	.0778	.0720
Guelph	.114	.0965	.0926
Stratford	.1218	.0983	.0934
Woodstock	.1307	.1091	.0995
Ingersoll	.1321	.1112	.1023

IV. The surplus power generated and transmitted with the object of serving the subsidiary municipalities would cost at the municipal sub-station switchboards—that is, without any allowance for the local distributing cost—as follows :

Cost per h.p. per annum at municipal switchboard :

Hamilton	$ 8.89
St. Thomas	15.09
Paris	12.19
Dundas	11.13
Mitchell	24.62
St. Mary's	19.67
Berlin	12.68
Waterloo	14.55
Preston	16.00
Hespeler	20.06
Galt	15.85

Present Cost of Steam Power.

The average costs of steam engine power developed for ten-hour day industrial use under the general conditions prevailing in the municipalities

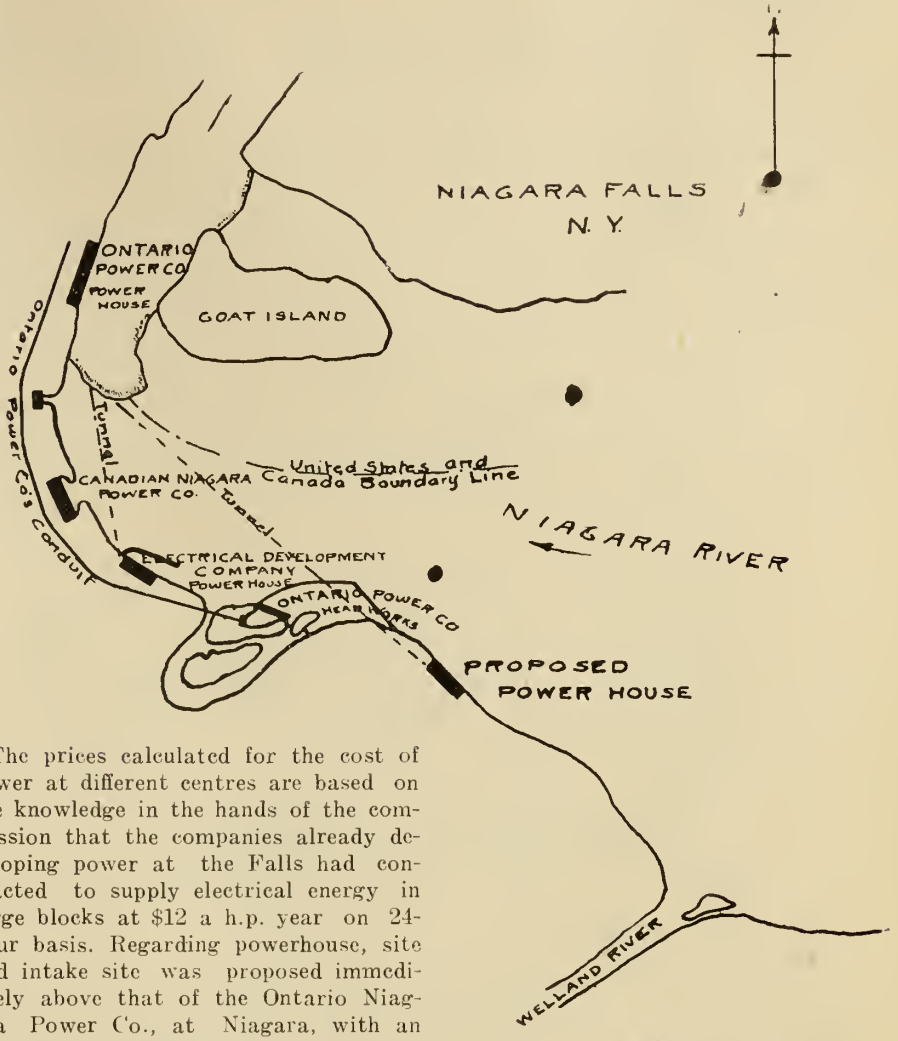
your commissioners represent have been investigated and computed as undernoted. The costs for a twenty-four hour service required in public service plants vary with the peculiar conditions of each undertaking, but they are, of course, much higher than those given below. The arc and incandescent lighting rates are reported by the engineers as varying considerably, but the undernoted scale is submitted by them as a fair approximation for ten-hour service:

	h.p.	
Indicated h.p. of plant.....	10	$111.50
Indicated h.p. of plant.....	25	78.00
Indicated h.p. of plant.....	50	57.50
Indicated h.p. of plant.....	75	53.50
Indicated h.p. of plant.....	100	48.00
Indicated h.p. of plant.....	150	40.60
Indicated h.p. of plant.....	250	32.00
Indicated h.p. of plant.....	500	27.80
Indicated h.p. of plant.....	750	24.00

These prices are based on a 75 per cent. load, which corresponds with average existing conditions.

The Government Commission.

The report of the Hydro-Electric Power Commission was signed by Hon. Adam Beck, chairman, Messrs. George Pattinson, M.P.P., and John Milne, the other commissioners, with an appendix containing the report of the engineer of the commission, Mr. Cecil B. Smith, on the operation, transmission and distribution of electric power. The report consists of a series of tables and maps setting forth with almost incredible detail and completeness, including all necessary calculations, a plan for distribution throughout the southern and western parts of the province of electric power from Niagara sources. It was recommended to purchase the right of way from Niagara to five separate divisions, with centres at Hamilton, Toronto, Guelph, London, and Windsor, as the market for 50,000 h.p. is available at once, and within five years 100,000 h.p.

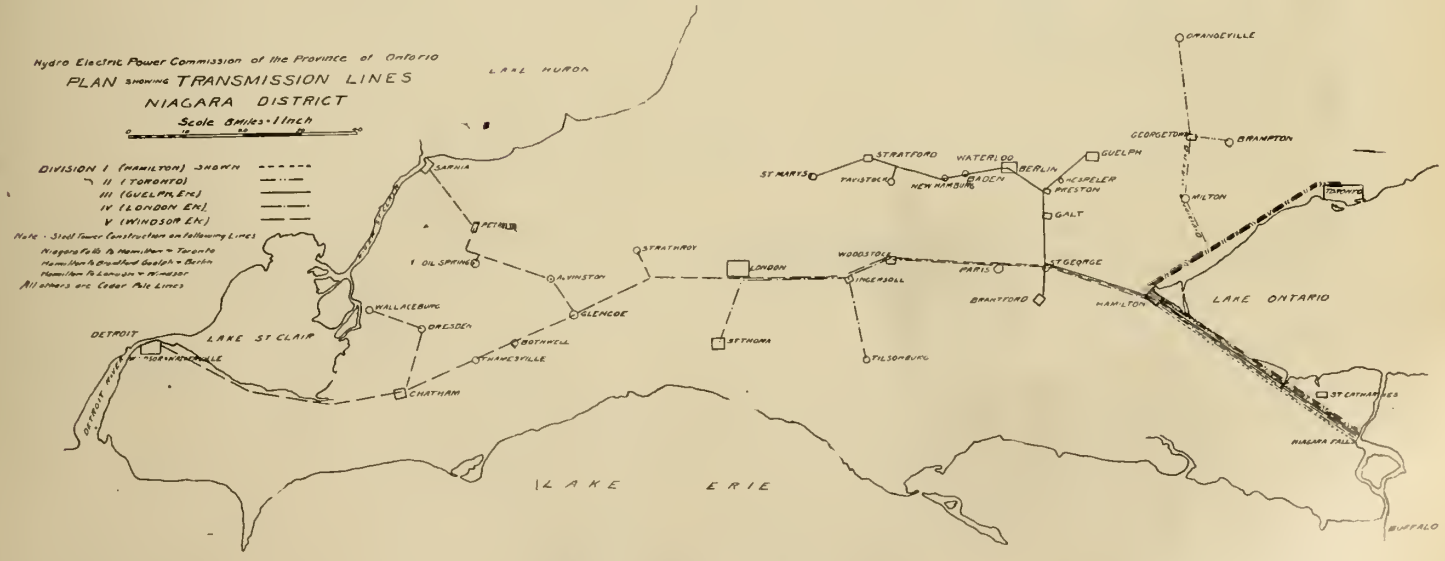


Site of Proposed Municipal Power House.

The prices calculated for the cost of power at different centres are based on the knowledge in the hands of the commission that the companies already developing power at the Falls had contracted to supply electrical energy in large blocks at $12 a h.p. year on 24-hour basis. Regarding powerhouse, site and intake site was proposed immediately above that of the Ontario Niagara Power Co., at Niagara, with an alternative site 18 miles west of the Falls, where double the head could be obtained, and therefore but one-half the water necessary to be diverted.

The transmission of power estimates are based upon the purchase of a private right of way over the entire district; 100 feet wide between Niagara and Hamilton, 66 feet wide between Hamilton and Toronto, and 33 feet wide alongside of highways or railways for the remainder. The class of construc- those from Niagara through Hamilton

(Continued on page 202.)



Proposed Transmission Line in Western Ontario.

Mechanical Reviews

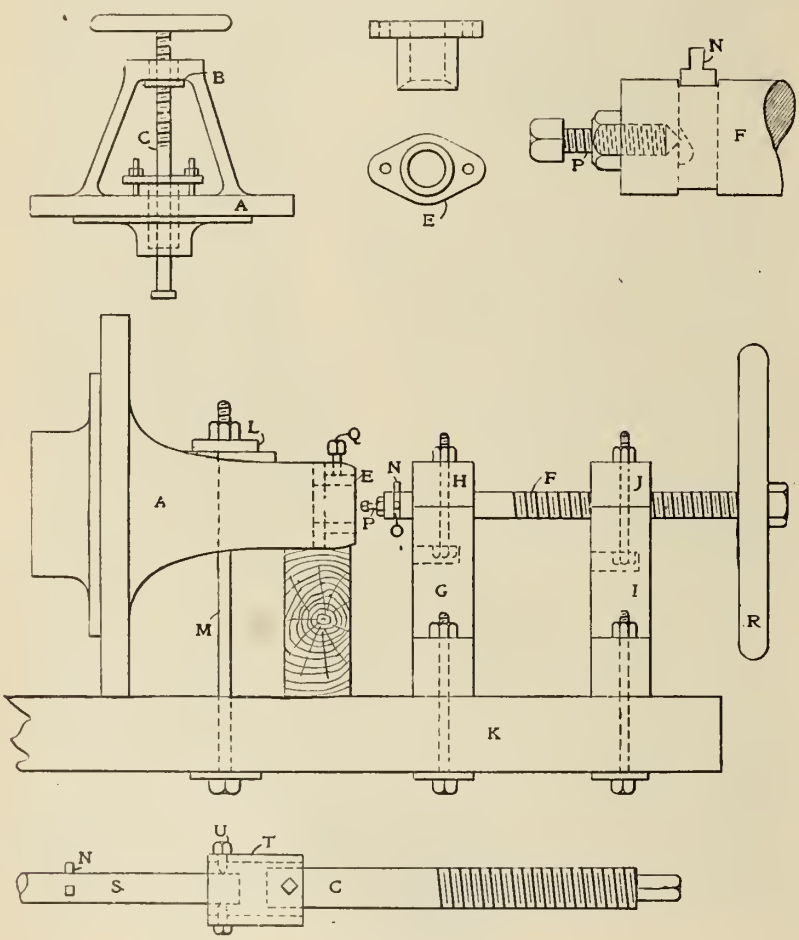
OPINIONS AND STUDIES WORTH NOTING

RE-CUTTING STRIPPED NUT AT SEA.

WHILE packing the main stop valve of the boiler of a British tramp steamer, I discovered accidentally that the nut (B) was nearly worn out. In the illustrations (A) shows the cap of the main stop valve with the yoke cast in one piece. The nut (B) for the screw (C) is let in from underneath and has a flange to take the thrust. It is held in place by the set-screw (Q), shown in the lower illustration. I took the cap off the valve and knocked the nut (B) out. In the storeroom I found an old winch gland, (E), of brass, which was a little smaller than (B). I wrapped a strip of tin around the body and drove it into the yoke. On measuring the screw (C) I found it to be about $1\frac{3}{4}$ inch outside diameter, four square threads to the inch. The screw (C) was in new condition, having been in use only about three months. A further search in the storeroom revealed an old valve spindle, (F), $1\frac{1}{4}$-inch diameter, the same pitch as (C), with the thread in good condition. I decided to use this, as it would save me considerable trouble in the cutting of the new nut over what I would have if I used the spindle (C).

I got a piece of plank, (K), 3 inches thick by 12 inches wide and about 4 feet long. This was trued up on one side and one edge so as to facilitate setting the different members of my threading machine. The cap (A) was bolted in place as shown, care being taken to have it square and parallel with the plank (K). An "old man" was then bolted to the plank and the nut (E) bored a little larger than the bottom diameter of the thread (C). The wooden bearing (G) was then put in place and its cap (H) fitted. A bar with a scriber on its end was passed clear through the cap (A) and nut (E). With this a circle was scribed on the face of (C). After transferring the circle to the other side, the bearing was worked out with a gouge. The bearing (I) was then bolted in place, scribed and worked out in the same way, but the hole in (I) was only the size of the spindle (F), at the bottom of the thread, while that in (G) was the size of the plain part of the spindle. The thread on the spindle (F) was then roughed with a chisel so as to cut a thread in the bearing (I) and cap (J). Both the caps (H) and (J) were put on loosely and gradually tightened down, while the screw (F) was rotated by the hand wheel (R). After the thread was cut in (I) and (J), the spindle (F) was taken out, the burs filed smooth and the square-threading tool fitted in the end. The end of (F) is shown enlarged at the upper right-hand corner. The square tool (N) was held in the hole by a set-screw (O) on the side. The pointed screw (P) and the inclined face on the tool (N) regulated the depth of cut. For the first four or five cuts the tool was driven back each time at the extreme end of the cut, so as to clear the thread on the backward stroke, but after the thread was about 1-32 inch deep this was found unnecessary. The thread was a good one, but it seems to me at this late date that I have taken considerably longer to describe the job than I originally took to do it.

I suppose while I am about it I better tell you how I would have cut that square thread if I had been unable to find that other spindle (F) which suited my purpose so admirably. I would have taken the spindle (C) of the valve and a piece of round steel or iron of suitable size, (S), say $1\frac{1}{4}$ inches or less in diameter by 18 inches long. I would have fitted up two plain bearings like (G) and spaced them a suitable distance apart. I might have put one on one side of the nut (E) and one on the other, as close as convenient for handling the threading tool. The next job would have been to make the threaded wooden journal, like (I), to fit the spindle (C). Then I would have taken a piece of pipe or old boiler tube and made a universal joint (T) by drilling holes clear through at right angles to each other. After threading these and fitting four pointed set-screws (U), I would have spotted the spindle end to suit two of the screws and the round rod to suit the other two. After fitting an adjusting tool, like (N), in the



HOW THE NUT WAS CUT.

round rod and coupling the rod and spindle together with the universal joint, the rig would be ready to put in the wooden bearings to cut the thread. —Dixie, in American Machinist.

REPAIRING A BENT PISTON ROD.

A COUPLE of months ago an engineer friend showed me that he had a badly bent piston-rod in a duplex triple-tandem compound pumping engine connected to a Holly system and operating condensing. The piston-rod that was bent was the outboard end of the intermediate, which is keyed to the crosshead, as is shown in Fig. 1. When I entered the engine-room the engineer had just taken off the outboard intermediate crank head; the crosshead key had not been drifted. I found it "clear home" with a 1-16-inch liner on the drawing side of it. We easily took out this key, and putting the piston-rod drift key in the slot at (J), a light tap with the soft hammer loosened the crosshead from the rod. I noted the looseness of the piston in the crosshead; also the key. I ordered a new key $\frac{1}{8}$ inch wider on its draft. We then took out the piston-rod and had it sent to the nearest machine shop. It proved to be out almost 3-16 of an inch and very near the taper fit to the crosshead. We turned it and chalked it where it was out, heated it several times and tried to straighten it, but we could not get the kink out entirely, so we concluded to turn off enough to

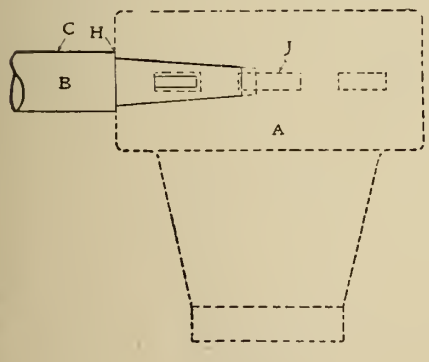


FIG. 1.

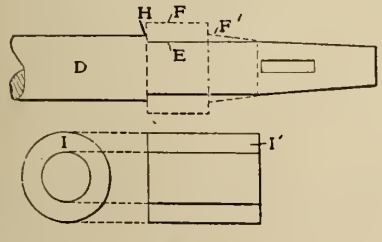

FIG. 2.

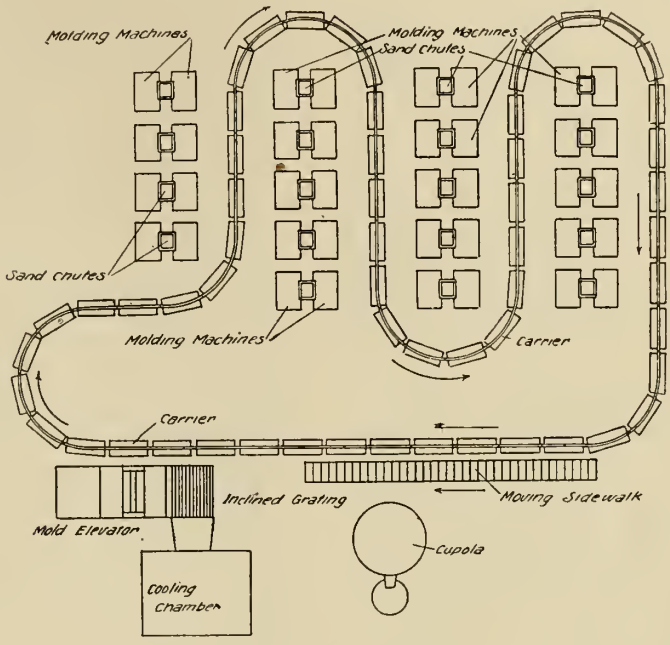
true it up, and in order to do this it was necessary to turn down the shoulder that is shown at (H), Fig. 1. This would tend to weaken the rod and the crosshead, so, after turning down the rod to the size shown at (D), Fig. 2, I found it necessary to turn down a portion of the taper from the keyway (G) to the shoulder at (H), thus leaving nearly as much shoulder as the rod had originally. A sleeve was made of round steel, large enough in diameter to exceed the original size of the piston-rod about $\frac{1}{8}$ inch, and long enough to fit over the entire portion of the rod that was turned down. This sleeve, or bushing, was bored, to drive onto the rod, tight enough to hold it for turning. The distance from the keyway to the original shoulder in Fig. 1 was measured and laid off with a pair of dividers. To make the taper on the bushing correspond with that of the rod, we turned the bushing until it appeared as shown by the dotted lines at (F) and (F1). After chalking this taper and trying the rod into the crosshead, we found it a very good fit, without the single application of a file to its surfaee. Then we had to take the bushing off the rod to put on the junk ring and to get the rod through the stuffing-box and the bushed gland, so we had the rod taken to the hydraulic press, and the bushing pressed off. We put the rod in the lathe again and eased off the fit as (E) with a file, enough to let the bushing ring on with a very light tap of the hammer. I put this arrangement together and drove the new key home, and it has been in continuous service since, giving entire satisfaetion, with a piston speed of 200 feet per minute against a head of 212 feet.—Power.

Do not forget that it isn't necessary to be disagreeable in order to disagree with the other man.

IMPROVEMENT IN FOUNDRY WORK

FOR centuries swarthy men have laboriously carried ladles filled with liquid metal to the most distant parts of a foundry. The new method is a complete reversal, for now the molds come to the cupola in an endless procession from morning to night. The result is, for small castings, a largely increased output at a great saving in cost.

The usual system in a foundry is an intermittent process. The greater part of the day is spent in making molds which are poured later on. This system works very well for large castings, but small castings can be made much quicker in a foundry equipped with the carrier system. In this method the melted iron is not carried to the molds, but instead the molds are brought to the cupola by the carrier shown in the diagram Fig. 1. This method not only saves time but also prevents the molten iron from cooling before it is poured.



Floor Plan of the Foundry

The operation of the new process is as follows: One of the molding machine operators opens the sand chute at the back of his machine and allows enough sand to fall into his machine to make one mold. He then turns on the compressed air which rams the sand better and quicker than can be done by hand. Then he turns another air valve which starts a pneumatic rapper constructed exactly like a pneumatic hammer. This causes the mold to vibrate and enables him to draw the pattern from the mold without any sand sticking.

The mold is then placed on the carrier which consists of a number of swinging shelves suspended from a track

overhead. These shelves are all connected to a chain which moves constantly in the direction indicated by the arrows in the diagram. When a mold reaches the moving sidewalk one of the pourers steps on the sidewalk with his ladle of iron and pours the mold. The moving sidewalk and carrier have the same speed, making it just as easy to pour as a stationary mold.

After it travels a little farther, during which the casting has set, it is removed to the elevator, which carries it up and dumps it on an inclined grating. This grating has a shaking motion which causes the sand to drop down through the bars, and passing through a hopper it lands on a rubber belt conveyer. It is here moistened with a spray and then discharged into a rotary sieve after which it is automatically conveyed to the sand chutes to be used over again.

The castings are too large to go through the inclined grating, but roll off the edge into the cooling chamber. After cooling they are tumbled and then separated in the automatic separator.—Popular Mechanics.

GREATER ECONOMY FOR THE GAS ENGINE.

ENGINES of the internal combustion type, though of comparatively high efficiency, are not nearly so economical as might be expected, due largely to the fact that the explosion temperatures and pressures fall far short of what they should be.

If we burn, for instance, an explosive mixture of gasoline vapor and air slowly and measure the heat developed, we would find that something like 22,000 heat units are developed by the burning of one pound of the fuel ; that is, enough heat is developed to heat 22,000 lbs. of water 1 deg. Fah. for every pound of gasoline burnt. Air, however, takes much less heat to raise its temperature than water, so that the same quantity of gasoline would raise the temperature of about six times 22,000, or 132,000 lbs. of air 1 deg., if the air were confined in a closed vessel.

At atmospheric pressure, 1 lb. of air occupies nearly 14 cubic feet, so that it will be seen that the burning of 1 lb. of gasoline would heat 924 cubic feet of air as much as 2,000 degrees.

This heat leaves the explosive mixture as fast as it is formed, and appears almost instantly in the water jacket or the cooling flanges—an evidence that it is there and might, if the proper means were found, be utilized.

Heat in its other form is work, therefore the most desirable way of getting rid of this heat would be to utilize it, make it do work.

The simplest way would be that in which a given quantity of fuel were made to heat a large quantity of air, calculating that quantity in such a way that at the temperature and pressures that now occur, the extra quantity would absorb all the heat otherwise wasted. That is, to use weaker mixtures.

The practical objection to this is that mixtures weak enough to absorb the waste heat and give it back as power are too weak to burn except under very high compression—and under very high compression the gasoline mixture will explode prematurely.

If the compression could be made in two stages, so that in the second stage the mixture enters the cylinder cool, the requisite compression might be had to work with mixtures of almost any degree of weakness.

In concrete form a double-ended cylinder like a steam cylinder might be used, the back end being fitted with three valves, two being the inlet and exhaust valves just like an Otto or four-cycle engine, while the third is a mechanically-operated valve through which the surplus air supply enters.

The front end of the cylinder would be an automatic pump acting every stroke —compressing the air to about 40 lbs. pressure and cooling it by passing it through a radiator, so that it would reach the working cylinder cool.

This pump acting every stroke would make the engine handle nearly three times the quantity of air per stroke and burn only the same amount of gasoline as previously required. The net result of Clerk's experiments was that instead of the engine utilizing 27 per cent. of the heat it utilized from 34 to 38 per cent. and avoided all the trouble previously encountered in over-heating and burning the valves, etc. The cylinder pressures are also correspondingly increased, so that for a given power the engine weight is not increased.

Another method does away with the air pump. In this arrangement a part of the exhaust is used over again, a tank being so connected up to the engine that just at the end of the working stroke, and while the exhaust is still under 30-lb. or 40-lb. pressure, a portion of the exhaust is allowed to enter the tank through an automatic non-return valve.

From the tank the cooled exhaust gases are admitted to the cylinder after the regular explosive charge has been drawn through the inlet valve and the regulation carburetter.

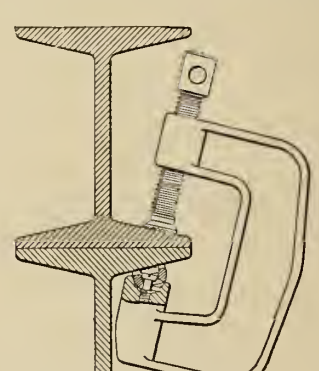
The objection to the use of the exhaust is that it takes a large radiating surface to cool it down properly, and also that the mixture weakened by it is not so combustible as with air.

A third method is to draw in the regulation charge through the carburetter and inlet valve and then, on the compression stroke, to inject the proper quantity of water ; that is, such a quantity of water as will be completely evaporated by the heat developed in compressing the charge. The objection to this is the extreme delicacy required in regulating the quantity of water used, as its presence in liquid form interferes with the ignition and makes the engine unreliable. However, in engines of upwards of 20-horse-power per cylinder it is quite feasible and greatly increases the power—though also the maximum pressures—so that when the attachment of water injection is applied, the crank and bearings, etc., have to be designed to stand from 50 to 100 per cent. greater pressure than ordinarily obtained in the four-cycle method of working. Merely as an illustration of the delicacy with which the water per stroke must be measured, it might be noted that the pump which would supply a 3x3 engine should not have a plunger displacement of over 3-16-inch diameter by $\frac{1}{4}$-inch stroke.

On a cylinder 6x6 this pump would still be very small, perhaps not exceeding $\frac{3}{8}$-inch bore and $\frac{1}{2}$-inch stroke, and even at that an ignition missed or a double stroke of the pump might put the spark, particularly the jump spark apparatus, out of commission. — Gas Power.

SCREW CLAMP WITH SPHERICAL ADJUSTMENT.

ROBERT GRIMSHAW sends a sketch of a clamp designed for holding objects, like the flanges of I-beams, that do not present parallel surfaces. It is made of a steel casting and has an "I" cross section with



An Adaptable Clamp.

stiffened back, and if sprung can be brought back to proper shape when hot, like forged ones. The spherical bearing on the under jaw allows all the adjustment out of parallel that is ever likely to be called for.—Machinery.

It is the little things, the trifles, which cut down the average of success possibility.

Foundry Practice

MODERN IDEAS FOR THE TRADE.

A TALK ON FOUNDRY CHEMISTRY*

By H. L. Bowers, Consulting Chemist and Metallurgist

UPON the fact that what is in other metals oftentimes a detriment, in iron becomes a positive blessing, if handled intelligently, hinges the whole subject of foundry practice. Probably no other business has seen so little advance over the conditions that existed forty years ago. Economies and certainties in casting iron should appeal as much to the foundryman as they do to the steel manufacturer. It is very important to the foundryman that he have an intelligent comprehension of the composition of the iron he is receiving.

Grading Iron.

The practice of grading by fracture has in the past been general, but it is unreliable. The grades used in foundry practice are (1) Silicon, 1.75 to 3.50, (2) 2.25 to 2.75, (3) 1.75 to 2.25, (4) 1.25 to 1.75. Practice in some furnaces is to offset high sulphur with high silicon.

Considerable difficulty would arise from such a substitution if the foundry using same did not depend upon chemical analyses to some extent. Oftentimes furnaces running upon bessimer iron have a run of iron high in sulphur, and in order to get rid of it it is run in on the foundryman in small quantities with iron of a better grade. Different furnaces have different systems of grading. What is No. 2 for one furnace may be No. 1 for another and a small foundryman using a grade of iron satisfactory to him may have it called No. 1, while another firm using the same brand may be buying the same grade of iron as No. 1 at a reduction of fifty cents per ton. The composition remaining the same, the fracture may vary. The No. 1 iron of a furnace using one material for pig bed, may be entirely different from No. 1 iron of another firm using a different material for the same purpose. Iron cast in chill molds shows nothing by fracture, besides phosphorus manganese and sulphur influence fracture. Sulphur and manganese may close the grain of a high silicon pig and the fracture of a very high silicon pig is often like that of a low silicon high sulphur pig. Frequently the presence of a high sulphur is shown by the presence of blow holes on top of the pig, but certain conditions may prevent this, so that as a method of determining composition, fracture is no guide. Buying and selling of iron on fracture is rapidly becoming obselete.

Discussion of Impurities.

Carbon may be called the controlling impurity and is of the most importance. Its effect on iron is varied and positive. In foundry iron it may vary from 2 1-2 to 4 per cent. The percentage of carbon determines the melting point of iron and without it the varied degree of strength and hardness could not be imparted to iron. In this respect it acts the same in cast iron as in steel. Free carbon or graphite is really a detriment to cast iron. In general, graphite represents that carbon the iron is incapable of holding in solution when cold. An iron containing no more carbon than it can hold its solution, is a white iron. This is the essential difference between malleable iron and cast iron. In one the essential carbon is burned out, in the other it is forced out and left in the casting. Combined carbon indicates the degree of hardness in iron. Combined carbon increases shrinking. Of two castings of the same composition of different thickness, the thickest will be softer owing to slower cooling and consequent forcing out of combination of carbon, while the shrinkage will be less. The thinner, owing to rapid cooling, holds more carbon in combination and greater shringage results. Carbon lowers the melting point, hence the greater the carbon the lower the shrinkage. Owing to the lower temperature the casting can be poured.

Silicon is not a desirable ingredient of cast iron. The amount of silicon in casting determines the amount of carbon which will be left combined in the solid casting. In other words, the total carbon remaining constant the combined carbon or measure of hardness varies as the silicon. Sulphur, phosphorous and manganese neutralise the effect of silicon. Silicon probably increases the fluid of cast iron and also causes the castings to peel well.

Manganese increases the affinity of iron for carbon, thereby improving the iron through the carbon. Manganese is desirable in heavy casting to about 8-10th per cent. and light casting to about 5-10th per cent. It reduces the affinity of molten metal for sulphur. It closes the grain of iron. One of the greatest difficulties in making stove plate is the necessity for uniform softness. The author here gave an instance of his experience. A casting which polished well and drilled all right in thin sections frequently took the edge off the tool used for milling the outside fitting edges. In other words, the thick portion contained particles so hard that the tool made no impression. At such times the complaint was that the iron contained sand. The analysis showed iron to be normal with the exception of manganese, which ran about 2-10th per cent. and on increasing manganese to 5-10th per cent. the trouble was remedied. The author's opinion is that under certain conditions in the absence of manganese a carbide of silicon or carborundum may be formed in the castings. Probably most foundrymen have had this experience with this so called "gritty" iron.

Phosphorous increases the fluidity of iron and corrects shrinkage and weakens the iron. It will harden iron and must be neutralized by silicon, hence an iron high in phosphorous and low in silicon is valueless for foundry pur- In heavy castings where strength is desired it should be low.

Sulphur combines carbon, erratically causing hardness and shrinkage by closing the grain and weakens the casting. Sulphur has been blamed for much it does not deserve. When the manganese is kept at a proper point there is little fear of sulphur going up to the danger point. The greatest difficulty, however,

* Abstracted from a paper delivered at the annual meeting of the Canadian section of the Society of Chemical Industry at the Engineer's Club Room, Toronto, April 6th.

in sulphur consists in the hard spots which show up when the iron is polished.

Some analysis were then given showing the composition of castings for various works. The actual analysis must be governed by the specifications required.

All efforts may to prevent the contaminuation of iron by sulphur must be directed towards the diverting sulphur from the iron to a slag during the process of melting, as once it has entered the iron it is hard to get rid of it. The percentage of sulphur may be regulated by the use of limestone. The limestone seizes upon the sulphur before it has a chance to enter the iron and is fluxed off. Fluorspar is also reckoned as a desulphurizer.

Other Considerations.

Limestone is generally used as a flux and as it ofttimes contains Fess should be watched carefully. Pig iron is coated more or less with sand and in order to get a free and rapid melting it is necessary to use a basic flux. The fact that lime eliminates sulphur makes it a valuable flux. Magnesia in limestone gives a pasty slag and dolomites should not be used in cupola practice.

Coke needs to be watched carefully as those running much over 1 per cent. sulphur are unsuitable for foundry practice.

Careful foundrymen consider the grade of molding sand. Too great a percentage of loam or lime causes a great loss by burning to the casting. A good sand should run high in silica, low in lime and fusible compounds or minerals. Analysis show Albany sand to contain Single O2, 82.42 per cent. and Hamilton sand 76.54 per cent. The Hamilton sand is a good sand for general work and heavy castings while the Albany sand being high in Single O2 is preferable for light work.

VENTING OF CORES*

By James A. Murphy.

FOUNDRYMEN could base interesting argument upon the subject of the proper venting of cores. Bad venting has always furnished a ready-made excuse for a bad casting by the molder; indeed, when he could think of nothing else to lay the blame on, the core was sure to come in for a bad character and the coremaker's ability was criss-crossed with suitable and expressive adjectives.

Not all molders recognize the degree of skill that is required to vent some

Fig. 1

crooked cores properly, nor do all coremakers realize how necessary it is to have vents through which the gas will flow easily and without any unnecessary obstruction.

The evolution of the air compressor, gas engine and automobile has set the brightest minds in the business experimenting, seeking a remedy for the poorly vented cores that cause such disturbances at casting time. The proper venting of this class of cores is a far more skillful operation than most people are ready to allow, and it is only seldom that the coremaker has the proper facilities to do the job properly. The core shop is the most neglected part of our foundries to-day and it is only within a few years that it has been given any notice at all. It is a hopeful sign of the times, however, to see foremen and employers in general waking up to its necessities and its possibilities.

The pulling of wires and soaped strings around corners as a means of venting is a thing of the past. The wax wire method of venting has come into our foundries to stay. All methods of wax wire venting are not by any means satisfactory.

The wax taper with a string of threads running through it gives very poor satisfaction, that with the wire through it is better, but its cost is an item of no small consideration, and many foundries prefer to do without it and continue to lose casting on this account. The object of using the wax, of course, is that the core while drying absorbs the wax, leaving only the string of wire which, when pulled out, leaves an open and free hole.

If the string gets burned on the end it is a difficult job to pull it, and if it breaks inside the core it cannot be extracted. An imperfect vent is the result and a possible blown casting.

The wax wires, Fig. 1, are the result of much experiment to do away with strings of any kind in the wax, in fact, to have something that was as nearly fool-proof as possible.

The element of cost was also a consideration, and the composition used is made at less than one-eighth of the cost of any wax on the market to-day. The illustration of the machine, Fig. 1, gives

Fig. 2

a fair idea of the process of manufacture. A helper will turn out enough of different sizes in about one hour to last 30 coremakers one day, so the cost of manufacture is infinitesimal, once the installation is made.

These wires are easy to handle, are not sticky except when hot, are as tough as twine when at the right temperature, and can be made in coils of any length or cut off in desirable lengths and laid away in trays ready for instant use. There is no waste, as the pieces not used, short ends, etc., are again put back in the machine and pressed out as new wires.

The thickness is regulated by the die. In practice I make them from 3-32 to 3-8 in., but any desired size can be made. The material is very light and I have known men not to use a pound all day venting the most complicated jacket cores for air cylinders.

Fig. 3

The skill of the coremaker is considerably minimized in producing a perfectly vented core, as it is impossible for him to do otherwise if he rams up a string of this wax in the proper parts of the core. It is not claimed that this

*Read at a meeting of the American Foundrymen's Association.

wax will take the place of rods, but its absorption by the sand in baking has a very decided tendency to strengthen the core.

Several cores that must be made in halves in order to be properly vented can be made in one piece by this process at a considerable saving of time and expense.

Since I designed this machine and brought this method of venting cores to what I consider a state of absolute perfection, in the shops of the Chicago Pneumatic Tool Co., at Franklin, Pa., blown cores are a thing unknown in our foundry where every casting is filled with them and where work of the most intricate character is the rule rather than the exception.

I cannot lay too much stress upon the time-saving qualities of this machine. Venting is at best a tedious and time-killing operation no matter how it is done, but with this wax all that is necessary is to run up the string in the proper place and the job is done permanently and well.

The ingenuity of the most expert designer in producing crooked orifices for which cores must be employed in the production of the casting, is defied, for as long as there is left any opening through which a small pipe can be passed a perfectly vented core can be made by this process.

Several foundrymen who have seen the process in operation have pronounced it one of the most important inventions for the cheap and safe production of intricate work.

Its cost of installation being very small, the cost of the material not worth mentioning, no waste material, the accessibility of all sizes of strings in any quantity at a moment's notice and the perfection of the cores that it is used in, are all points very much in its favor of being later as universally adopted as the core-making machine.

I consider it absolutely indispensable in shops which make a specialty of pump, engine, air compressor, gas engine, automobile or other intricate or delicate work. In several of these shops its savings in the course of a year would run well into the thousands of dollars.

The Making of a Nine-Foot Valve

By Robert Shirley

FOR controlling the flow of water to the turbines of the Ontario Niagara Power Co., at Niagara Falls, Ont., it is necessary to introduce a valve in a 9-foot penstock, and the accompanying illustrations show the method of making the patterns and the molds for these valves. The work was done by the Pratt & Cady Co., of Hartford, Conn. Each one of the gate valves weighs 126,000 pounds, and they are the largest valves thus far constructed. The complete valve assembled on the floor of the shop is shown in Fig. 1, which also shows the gears for the controlling mechanism, which is operated by electricity. The body of the valve on the cars ready for shipment is shown in Fig. 2, and this view gives a very good idea of the size of the pieces and the rigging of the castings.

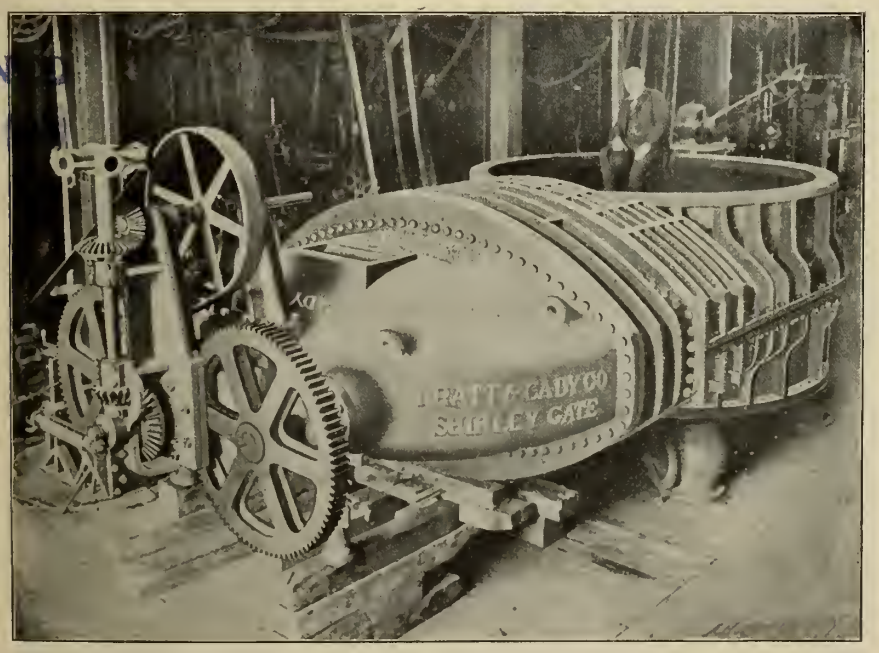


Fig 1—The Finished Valve

For turning the circular portion of the pattern a regular Fay & Scott lathe was used, which was built to swing 66 inches over the gap in the bed, but as some of the pieces were 132 inches in diameter, it was necessary to turn the head around and raise it 20 inches. The head was raised to save cutting a hole in the pattern shop floor. The chuck used in turning the work was the large iron chuck furnished with the lathe, to which a wooden face-plate is attached.

A drawing of one-half of the valve body is shown in Fig. 3. The location of the ribs can be very plainly seen. The body was made in halves so as to

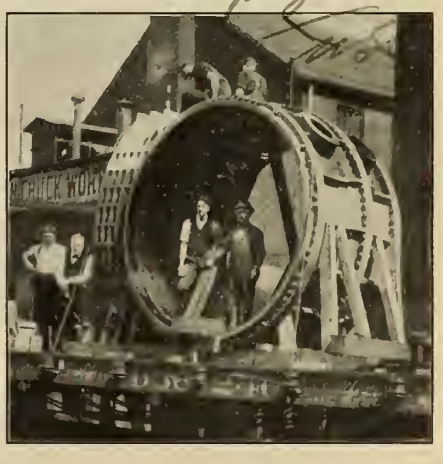

Fig. 2—The Valve Body

leave its own core, with the exception of the internal ribbing, which was taken care of by dry sand cores. The horse shoe-shaped flange, (A), which is located at the middle of the valve, was made first as a foundation upon which to build the pattern. The drum of the body was next turned up and placed in position at the circular end of the horseshoe-shaped flange.

The flange (B) was cut out on the inner side to conform to the shape of

the outside of the valve body or neck of the valve, and was then placed in position. Staves were carried from the neck flange to the drum of the valve and made fast there. This gave the outline of the valve body. The outside ribbing was then put on over the staves and made fast by screws from the inside. The ribbing was also fastened together, so that it would be drawn from the mold in one piece.

The valve was molded with the round flange down. The sides forming the body or neck of the valve were so located that one came under each rib, as indicated by the dotted lines in Fig. 3. This left a space between the ribs so that the molder could ram down between them and secure each pocket as he went along. The annular flange was made in sections so that it could be drawn in after the pattern had been drawn from the mold. These sections were also screwed firmly in place while the mold was being rammed up on the outside.

Before the inside of the mold was

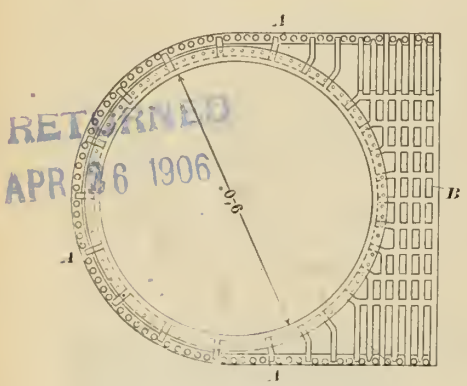

Fig. 3—Drawing of Valve Body

rammed up all screws were removed, both from the ribbing and the circular flange. A plate which had been previously prepared to carry the prints for the inside pocket cores was then put in place, all of the prints on the plate were numbered and the cores numbered to correspond. This was done to facilitate setting the cores and to avoid mistakes in the foundry. The prints were all put on with dowel pins so that they come away with the cope, thus leaving the mold free to be dressed. After the pattern was drawn (the inside of the ribs conforming to the outside of the body), all that was necessary was to scrape off the superfluous sand to the level of the ribs and the inside core gave the required thickness of metal.

The general construction of the valve bonnet can be seen by referring to Fig. 4. The bonnet was made in green-sand with a dry-sand core. The pattern was made as though it were expected to leave its own core, and the interior of the pattern then used for a core-box. This was done to save the expense of making a core-box. The dotted lines below the upper right-hand view in Fig.

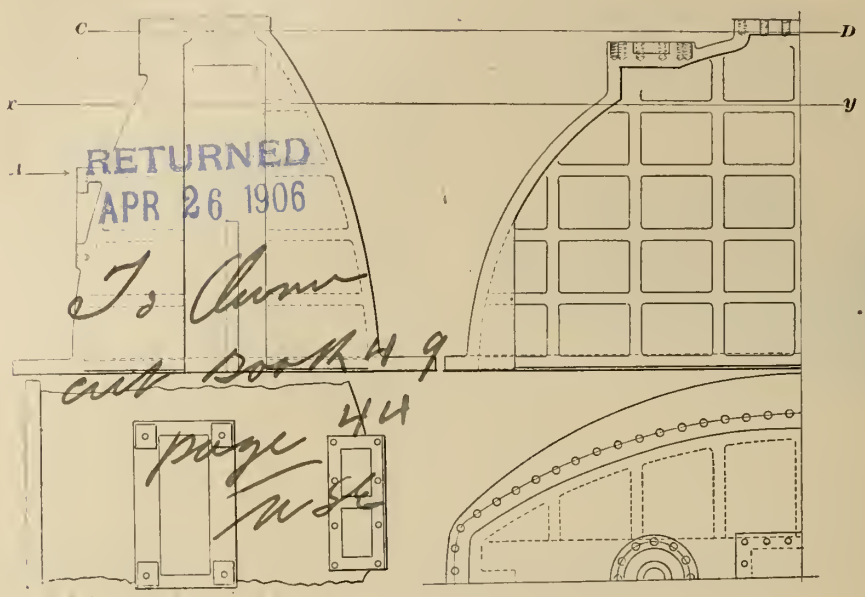

Fig. 4—Section of Valve Bonnet

4 show the print that was fitted into the bonnet when it was used as a pattern, also the corresponding piece which was fastened by pins to the flange of the bonnet when the pattern was used as a core-box. By this device the core was made to fit the prints.

In making the core the pattern was set on a cast-iron plate. The top part of the pattern was made with a joint on the line (x-y), so that the upper part could be removed. This provided ample room for a man to work inside. The inside ribbing was all made in separate pieces, and before the core was rammed up all the pieces except the bottom longitudinal ribs and the first row of the vertical ribs were removed. The sand was then rammed to the top of the vertical ribs, scraped off flush, and the second set of longitudinal and vertical ribs screwed in place, when the ramming proceeded as before. This continued until the line (x-y) was reached. The top part of the bonnet was then replaced upon the pattern, being guided in place by dowel pins. The cap above the line (C-D) was then removed, thus providing ample room for ramming up the top part of the core. The screws holding the various ribs in

Fig. 5—Mold and Core for Body Extension of Valve

Fig. 6—Mold Ready for Cope

place were then taken out and the pattern lifted off. As the ribs were withdrawn from the core the recesses formed were filled with blacksand to prevent the sagging of the pockets. The core was then ready for drying.

The greatest possible amount of care was taken in the pattern shop to avoid mistakes in the making of the various patterns required for a valve of this size, and the results were very successful.

As has already been stated, the valve body was made in two parts, which were bolted together at the centre. This body is heavily ribbed both inside and out and hence it is a very delicate piece of work for the foundryman. A view of the mold for one-half of the body is shown in Fig. 6. A large central core is nine feet in diameter, and both the core and the mold are of green-sand. After the pattern is drawn the central core, which is made on a plate, is removed to permit the proper dressing of the mold. As the mold is made in a pit in the floor the only rigging necessary was a plate for lifting the core and a flask for the cope. The rib pockets in the drag, being of green-sand were all securely rodded. The rib pockets in the cope were a much harder proposition to handle and hence were made with dry-sand cores which were tied in place in the cope. Every point and every core was numbered to facilitate the setting. The cope with all its cores in place weighed about 35 tons.

The mold for one of the distant pieces for the throat of the valve is shown in Fig. 5. The piece is also called a body extension. The mold is of green-sand and the picture was taken just as the dry-sand core was about to be lowered into place. On the right side of the picture is John Wuseh, foreman of the foundry, and on the left of the core Edward Mullhouse, assistant foreman. The pockets in the core are very deep and hence considerable care had to be taken in drying to prevent them from sagging.

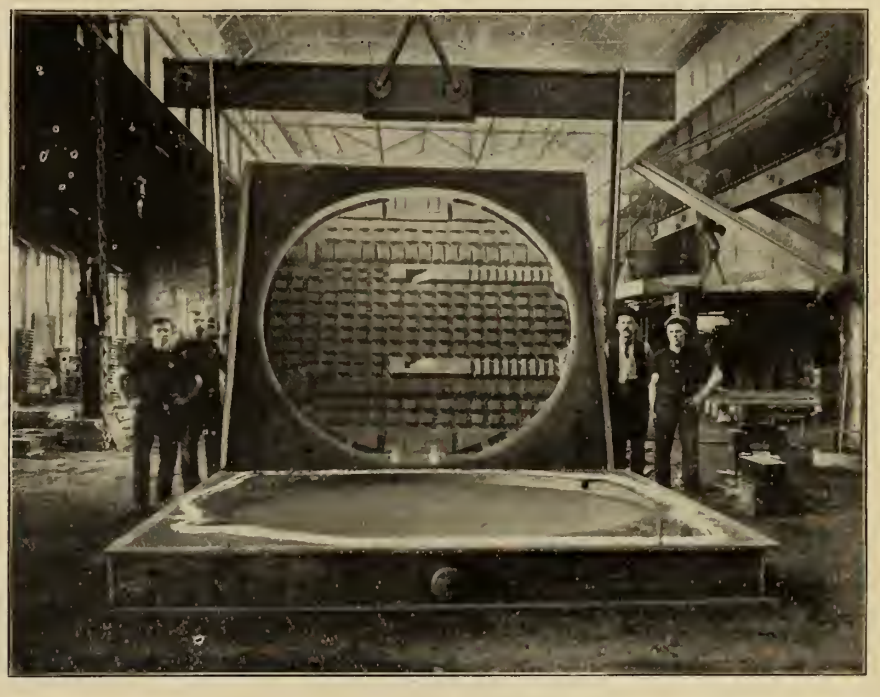

Fig. 8—The Mold for Valve Gate

Fig. 7—Mold of valve Bonnet

The mold for the valve bonnet is shown in Fig. 7. The drag is made in a pit, and in the illustration a dry-sand core is shown in place. The flask upon the lower flange of which the men are seated is the cheek. It was impossible to get a view of the inside of this part of the mold.

A view of the mold for one of the gates is shown in Fig. 8. The face side of the gate is in the drag to insure a good clean surface for the reception of the brass seat rings.

For the reproduction of this article and for the use of the illustrations Canadian Machinery is indebted to the courtesy of Wood Craft, Cleveland, Ohio, in the columns of which it originally appeared.

Making a Pair of Involute Gears

By John Carr, Hamilton

A DESCRIPTION of work actually done and method of doing same is probably more interesting to most readers of Canadian Machinery than theories and formulas. While theories and formulas are necessary, the practical application of those theories and formulas is vital to the success of any department of mechanics.

The pair of gears described were made for the London Machine Tool Co. for heavy punch. The large gear has 55 teeth, small gear 16 teeth. Shape of teeth involute 15 degrees. Both gears are shrouded to within $\frac{1}{8}$-inch of pitch line. Pitch 1.25 diametral. Web of large gear 2 inches thick. Rim 2 inches thick. Face of teeth 6 inches. Shrouding flange 1 inch thick. Four-tooth clutch on one side of web. Hub 16 inches diameter. Bore 7 inches.

Web was built of two layers, grain of wood running toward centre. Rim built up in segments as shown in Figure 2, all joints being lapped. The shallow hub with clutch fastened permanently at centre, binding centre of web together. This hub turned up with web, teeth of clutch worked out and planted on separately. On reverse side one piece 1 inch thick was fastened in centre to make large fillet where the hub joins the web. The body of hub was built up in segments and head let in; this hub left loose to lift off with cope when molding, and kept in position by brass dowel pins. Shrouding flanges were built up in three layers of segments and fitted with brass

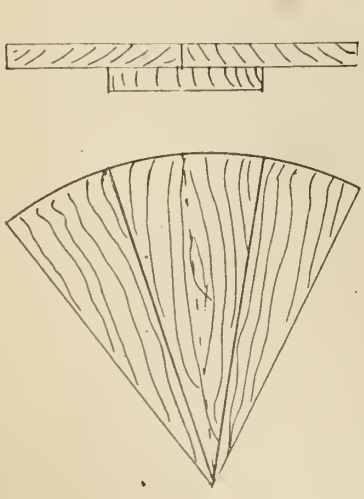

Fig. 1.

dowels, both flanges being left loose to give molder opportunity to watch teeth when drawing pattern out of sand. Never depend upon two layers of segments for a pattern you wish for permanent use; it will not stay straight.

Teeth for these gears were cut in a box, the curves of box having been made to template taken from drawing; one end of box made slightly smaller than other to allow for draught. The rim was divided accurately and teeth set to

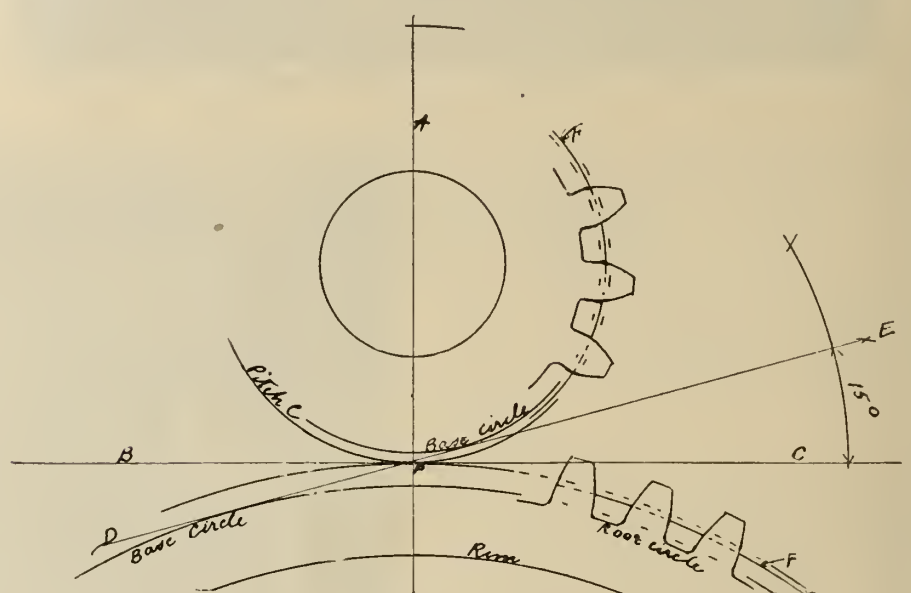

Fig. 3.

line, then screwed in place through rim. The gears were laid out as shown in Figure 3.

(A) is a line passing through centres of both wheels. (P) is the point at which pitch circles meet. Through this point line (B C) is drawn at right angles to (A). Pitch circles determined by formula are also drawn through this

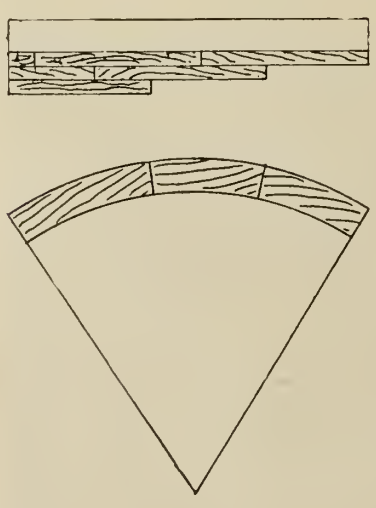

Fig. 2.

point. Through this same point is also drawn the line of obliquity in this case fifteen degrees as shown (D E). From centres of gears base circles are drawn touching this line, templates being made to these base circles. The involute curve is drawn mechanically by unwinding a string off templates, template being tacked in proper position on drawing. Tooth is completed inside base circle by drawing radial lines to root circle. When one tooth of each gear is completely drawn, templates are made exact to drawing, from which templates shape of boxes for working teeth are cut. Small leather fillets were run in at roots of teeth. The circular pitch being coarse about two and one-half inches, three-sixteenths clearance was left on pitch line, also in depth of tooth.

Formula, large gear.—To find pitch dia. $55 \div 1.25 = 44$ ins. To find outside dia. $(55 + 2) \div 1.25 = 45.6$ ins. To find circular pitch $44 \times 3.1416 = 138.23$ ins.; $138.23 \div 55 = 2\ 513$ ins.

Formula, small gear.—To find pitch dia. $16 \div 1.25 = 12.8$ ins. To find outside dia., $(16+2) \div 1.25 = 14.4$ ins. To find circular pitch, $12{,}8'' \times 3.1416 = 40.212$ ins.; $40.212 \div 16 = 2.513$ ins.

Three rapping plates were let in on cope side and three draw plates threaded five-eighths on under side of web. Finished with three coats black shellac,

---

There is always a best way of doing everything, even if it be to boil an egg. Manners are the happy ways of doing things; each one a stroke of genius or of lo e, now repeated and hardened into usage.—Emerson.

It would be an unspeakable advantage, both to the public and to the private, if men would consider the great truth that no man is wise or safe but he that is honest.—Sir Walter Raleigh.

Driving Gear for Wood Planing Machine

By T. C. Robertson.

THE power required for the feed of wood planing machinery is somewhat difficult to determine, owing to the variety of work done on a single machine. The speed per minute may vary from 10 to 80 feet, and the amount of resistance offered may admit of almost as great variation. The only safe method of design is to take the maximum load, and this is a matter of considerable difficulty, as the conditions vary so much that only experience can fully determine what is reliable.

In order to obtain pulleys, gears and shafts of sufficient strength it is, perhaps, the best way to begin with the size of belt used, and this has been pretty well established by experience on the different types of machines. The greatest possible power delivered by the feed belt will determine the proportion and strength of machinery leading up to feed rolls. We will take, for example, the case of a planer and matcher with four cutter heads, say top and bottom head 15 in. long, side heads 6 in. long.

Referring to diagram, we will take power from countershaft which makes 900 revolutions per minute. On this shaft is mounted a pulley (A), driving on pulley (B). On the end of shaft on which (B) is fastened there is a pinion (C), geared into a larger wheel (D), mounted on intermediate shaft containing another pinion (E), which is geared to wheel (F), fastened to feed roll which acts upon board being fed through. This completes train of gearing from countershaft to feed roll.

Having determined feed roll to be 9 in. diameter, and rate of feed per minute to be about 50 feet, we find that roller must make about 20 revolutions per minute. In the present example we obtain pulleys 5 in. and 18 in. diameter; two gears 18 in. and 20 in. diameter, and two pinions 5 in. and 6 in. diameter on pitch line.

As we must find a basis of calculation, this is best obtained by finding horse power of belt, which we find by following rule $H\,P = \frac{V \times B}{800}$ in which V = velocity, B = breadth 4". As the countershaft makes 900 revolutions, and pulley is 5" diameter, velocity would be

$\frac{900 \times 5 \times 3.1416}{12} = 1178$ feet per minute,

$\frac{1178 \times 4}{800} = 5.79$, say 6 H.P. Let us now obtain revolution at which gears and pulleys revolve. A = 900 revolutions, B and C $\frac{900 \times 5}{18} = 250$ R.P.M.; D and E $\frac{250 \times 5}{20}$ = 62.5 R.P.M.; F and G $\frac{62.5 \times 16}{18} = 20.8$ R.P.M. of feed roll.

We here must recognize a well-known mechanical principle that the slower the movement by which any given amount of energy is transmitted the greater must be the strength with which the moving parts are constructed. Gears (F) and (G) must therefore be the strongest in the train. In order to obtain load on tooth of gear it will be necessary to find lienear velocity of roller on which gear is attached.

$20.8 \times \frac{9}{12} \times 3.1416 = 49$ ft. per min., say 50 ft.

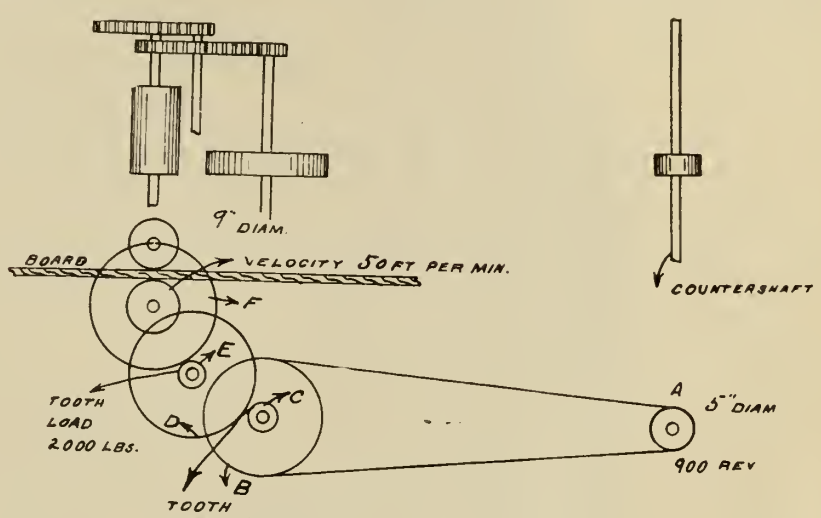

Diagram showing Train of Gearing.

6 H.P. = 33000 × 6 ft. lbs. per min. Velocity of board 50'; pull on board $\frac{33000 \times 6}{50} = 3960$, say 4000 lbs.

The load on tooth of F and E $= \frac{4000 \times 9}{18}$

= 2000 lbs. load on C and D $= \frac{2000 \times 6}{20} =$ 600 lbs. = total load.

The next step will be to determine proportion of gears E and F. Lewis' well-known formula will give us pitch—from which other parts are proportioned—as follows: W = 3 P' F Y, in which W = 2000 lbs. in present example S = 8000, or safe working stress at 100' per min.; for cast iron F = face of gear which we will assume to be 2¼", Y = factor of strength for 15° involute number of teeth we may assume at 54.

$Y = 0.124 - \frac{0.684}{54} = 0.124 - 0.0127 = 1113$

2000 lbs. $= 8000 \times P' \times 2\frac{1}{4} \times .1113 -$

$P' = \frac{2000}{8000 \times 2\frac{1}{4} \times .1113} = \frac{1}{1.0017}$

Approximately 1" pitch nearest circular pitch = 1.0472, corresponding to 3 diametrical pitch; number of teeth = 3 × 18 = 54 which corresponds to diam. required. Proportion of teeth may be obtained from pitch as described in Brown & Sharp's catalogue, or from article in Canadian Machinery of May, 1905.

The load on gears (C) and (E) is lighter and may be worked out in similar way, giving approximately 4 diametral pitch.

It should be observed here that pinion (E), if cast iron, is the weakest wheel, owing to teeth being somewhat undercut. If steel is used in pinion (S) would equal 20,000, in which combination the wheel (F) is the weaker and would therefore be the measure of strength. In calculationg size of shaft on which roller is mounted we have a more difficult problem, as twisting and bending moments enter into it. For the present example we may be safe in using a simple formula if the gear is kept close to bearing to avoid excess of bending strain:

$$D = \sqrt[3]{\frac{P\,L}{K}}$$

in which D = Diameter in inches, P = twisting force for cast iron 2000 lbs., K = coefficient value 1700, D = length in inches (9")

$\frac{2000 \times 9}{1700} = \sqrt[3]{10.6} = 2.15$" approx.

Card Index for Follow-Up System

By W. H. Stevens.

UNLESS you catch the apples as they fall it is useless to shake the tree.

Just so, unless you are prepared to follow up each enquiry received, you may as well not advertise. If but a few inquiries are being received, one may manage to follow them by recording in a book, or by keeping all the letters, reports, etc., together, and apart from other letters, until the matter is settled. But with constant inquiries, the task of following these by such cumbersome methods is so great, that only very important matters are likely to receive proper attention and that only with a large amount of work, while a large portion of advertising results is wasted.

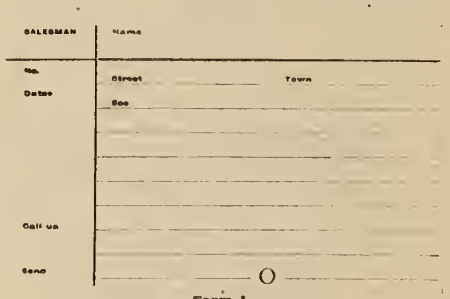
With the card system any requirement may be met, large or small, simple or complex. The following suggestion from systems actually in use, both in its entirety and in its various parts, may be of service, but of course must be suited to conditions wherever adopted.

An inquiry is received. A card or slip about 5 in. x 3 in. (larger if necessary) see form 1, is made out by clerk, (in duplicate if desired) containing name, address, correspondence number, and any particulars desired, also a note of the inquiry and reply. This is filed in a diary tray, vertically, wherein are cards called guides, having projections for months on one color, and for the days of the month, 1-31, on another. If your reply or quotation is dated say the 20th, place the card behind the guide card for the 23rd or 24th, or as far ahead as you wish to allow for an answer. When that day comes, if an order or reply has not been received meanwhile, write again and note on the card, putting it forward in the tray. If

Cabinet for Index

you have a traveler to assist you by calling, a duplicate of this report is handed him with instructions to call. He reports his call on a similar slip, a pad of which he carries in a small leather cover, while he retains a carbon duplicate for his further use. All these slips should be clipped together, and moved forward as the matter is followed, until a definite result is obtained.

It is often desirable to have at the same time an alphabetical index of these inquiries. In this case two methods are used; one, a duplicate or report slip is made out with carbon and filed alphabetically; but while this gives the result with no extra writing, a large number of slips accumulate, making quick reference difficult and taking extra space; the other way is to make out a card (see form 2) showing any particulars desired (i.e., credit, payments, statistics, customers' requirements, etc.) and a note of the inquiry and your reply. When another report or letter is received, this is entered on this card. By using both sides of this card, from 10 to 30 or more brief reports may be

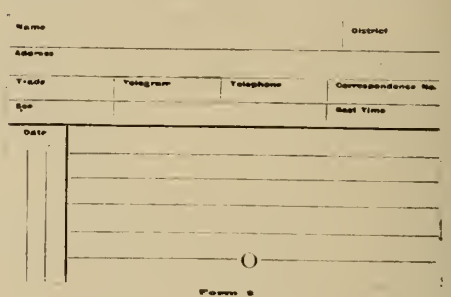


Form 1.

entered on one card, and thus the whole record may be quickly referred to by a principal.

All letters written or received which require entering on this alphabetical list, are stamped "Report" by the one who opens or writes the letters, and the correspondence clerk (or other clerk to whom the work is assigned) makes out a report. This is entered on the customers' alphabetical list and then placed in the diary tray. If the vertical numeric filing system with separate copies is used, the correspondence number is put on the slip and then on the alphabetical card when first made out, and is then convenient for reference from these lists without looking in the correspondence index. Since by this arrangement the letters are filed away at once, they are always ready for immediate reference by anyone requiring them, and not side tracked or kept out by manager or other official, causing great inconvenience to anyone wanting such letters.

The traveler may, with advantage oftentimes, have a diary tray and a list of customers also, and form 2 may serve for both—the traveler himself entering reports of his calls on his customers'



Form 2.

card and of letters which the clerk reports to him, following these up by means of the diary. When not in use they are filed by district, so at any moment he may have together all the cards in one town.

When it is necessary the alphabetical customers' list may be classified automatically in a variety of ways, i.e., in different colors for different classes of trade, or if such classifications are more than four or five a small tab on the card in different positions shows this classification more easily. A tab card is sometimes used to distinguish between prospective and actual customers, the tab being cut off when an order from the prospective customer is received, or the prospective and actual customer may be in two separate lists. Again, by use of cards with 12 or 15 tabs on each, each tab may indicate a different product. If a circular relating to one of these products has been sent out the tab representing that product may be marked, and when the order is received, the tab would be cut off, showing at a glance what circulars had been sent and what products supplied to each customer.

FORESIGHT

Foresight is a little-discussed virtue, though it is a fundamental one. The habit of looking ahead has made many lives successful. Lack of this same quality has turned hundreds of shiftless, improvident persons upon the world.

* * *

No matter if you are hidden in an obscure post, never content yourself with doing your second best, however unimportant the occasion.—Genl. Phil. Sheridan.

The Late John Bertram

CANADA'S FOREMOST MACHINE TOOL MANUFACTURER.

" Though old, he still retained
His manly sense and energy of mind.
Virtuous and wise he was, but not severe,
He still remembered when he once was young."

WHAT the name of Carnegie is to the iron and steel trade of the United States, and that of Edison or Westinghouse to the electric and allied industries, so has the name of John Bertram, of Dundas, been to the machine tool interests of Canada. From the quiet serenity of a peaceful old age and the fruitful enjoyment of the success of a well spent life, John Bertram was called suddenly as he was preparing to leave his residence for his office on the morning of April 4. Without a moment's warning the summons came, causing sorrow, deep and lasting to his immediate family and friends, and regret, genuine and sincere, not only to his fellow townsmen, but to the entire manufacturing interests of the Dominion. While the name of John Bertram will live in the large and important industry that bears his name, those who knew him personally will cherish his memory on account of his attractive personality, rather than as the man, who, more than any other, made the name of his adopted town known from the Atlantic to the Pacific or the man who stood the test as a captain of industry or as a leader of men.

The late John Bertram, of Dundas, Ont.

To be respected and esteemed is given to many, but to stand in the fierce light that beats upon a man in an exalted position and be beloved by all, comes to few, but such was the case with the late Mr. Bertram. The silent music of his life, his bright blue eyes, clear complexion, the native Scotch accent, his kindly smile and fatherly interest in others, all united in drawing men to him and made him one who touched the inner lives of his fellows. While genius was in his make up, energy, perseverance, courage, and integrity were the dominant qualities that after his landing in Canada were to win the name and fame that came to him and that placed him in the forefront of the machine tool trade of the Dominion.

On Sept. 13, 1829, John Bertram was born at Eddlestone, Peebleshire, Scotland, his ancestors being pioneers in the millright industry in the south of Scotland. Until fourteen years of age he attended the parochial schools there and during that time he received his first inspiration in mechanics in operating a foot lathe belonging to his grandfather. He soon became an expert turner and was a great favorite amongst his classmates whom he kept supplied with spinning tops or peerics, as the boys called them. In his fourteenth year he moved with his grandfather to Galashiels, a town celebrated in that day for the manufacture of tweed cloth. After two years attendance at school there he became an apprentice with his uncle, Thos. Ainers, of the Waverley foundry.

The life of an apprentice in those days had few of the attractions of to-day. The time to be served was five and a half years and the remuneration during the entire period was six shillings a week. Besides this, the work carried on in the early forties was not easy. If the aspiring young machinist, whether from necessity or principle, refused to pay his footing (which meant a glorious time in some public house) it was counted against him. He dare not give any opinion on a mechanical subject, and high words and worse were his common lot. Happy was the apprentice who had the grit to stand his ground or hit back if required and consider it as the general order of things. When young Bertram suggested to a journeyman

an improvement in the shape of cutting tools instead of the old grubo hoes, the latter stopped, amazed at his impertinence, and said: "Johnny, when you are a journeyman you can shape your cutting tools as you think fit, but don't dictate to me."

In later years Mr. Bertram felt that life in his youth was in one sense a good training school, as he always profited by the mistakes of his elders and never harbored any hard feeling, for in four years he found his place and was able to exercise his own judgment.

The machines in the shop where his apprenticeship was served were of the most primitive type, the lathes had wooden shears and turning was done with slide rests. The proprietor, a skillful engineer, was determined on a change, and installed a set of lathes with ponderous iron frames set upon heavy stone foundations. They were powerfully geared. This change was justified on account of the future class of work which was made a specialty by this establishment. The class of machinery made until this time was textile machinery, such as carding, spinning and the complicated machines required for producing the fine woollen tweeds which have made a world-wide name for this district. Mr. Aimers decided to drop out of the competition with English makers of textile machinery and confine himself principally to steam engines, water wheels, shafting and gearing, as at this time a large number of factories were built on the Tweed and its tributaries. In this class of mechanics the young apprentice had good scope for his ability and made many improvements on machine tools and appliances.

Like all imaginative mechanics he had a hobby, and being always attracted by electric science, in 1848 he spent his spare evenings constructing a direct current machine. In partnership with a brother workman, they prosecuted this hobby for a time, but his friend became alarmed when he saw the expense and realized what lay before him, and withdrew. So Bertram plodded on alone, constructed a machine for insulating the wire, which completed over one hundred feet every evening and finished his electric machine in a few months.

In May, 1852, Mr. Bertram entered married life, taking as his partner, Elizabeth Bennett, fron Roxboroughshire. About that time he made up his mind to come to Canada and with his young wife he set sail from Glasgow on a barque of 1,000 tons register, belonging to the Allan Co. A few weeks before landing a large part of Montreal city had been burned and presented a desolate appearance, so they decided to go to Toronto, arriving in the city by the steamer New Era on a beautiful morning. To use Mr. Bertram's own words, "Dressed in our Sunday braws, we stepped on the wharf at the foot of Young street. There was no esplanade, no railway and none of the landmarks that characterize the city to-day, and Toronto did not look very inviting at that time. While looking at the novel surroundings, so unlike the Broomelaw pier, our appearance attracted the attention of Mr. Duff, of the Inland Revenue Department, who was watching the arrivals. He came up and asked us where we came from and, finding I was a machinist, said: "'Go straight to Dundas and you will find a situation in the John Gartshore foundry.' Dundas? Dundas? I inquired. I never heard tell of it. 'Well,' said Mr. Duff, 'continue on the boat to Hamilton and you will find Dundas.'"

The manager of Gartshore's foundry was the late Willian Gill, Esq., a Galashiels' engineer and well known at that time to Mr. Bertram, who was immediately engaged. The tools here were of a very antiquated pattern, except an American lathe, charge of which was given to Mr. Bertram. It had no changeable feed and required fifty turns of the work for one inch of traverse. The mechanical genius of the man exhibited itself here and he immediately set to work to put a variable speed on the lathe and so doubled the output. At this time these works were building the engines for the steamer "Queen of the West," and latterly the first engines of the Hamilton water works, of which a large part of the work was machined by Mr. Bertram. During these years not only was his inventive ability given scope, but also the development of a keen business sense was begun.

In 1865 he joined partnership with Robt. McKecine under the title of McKecine & Bertram. This business was carried on for twenty-one years and when the senior partner retired it was continued as John Bertran & Sons and later incorporated as a joint stock company. During all this time new lines were being constantly added to the output, improvements made in existing methods and business reached out after from ocean to ocean until the firm became the best known of its kind in the country. Last Summer the business was incorporated with the Niles-Bement-Pond Machine Tool Co., the largest builders of machine tools in America, having the parent Niles works in Hamilton, Ohio, the Pond works in Plainfield, N.J., the Bement works in Philadelphia, as well as the electric crane department.

During his many years residence in Dundas the late Mr. Bertran was one of its foremost citizens and exercised a keen interest in promoting its welfare. He was a councillor for many years and held the offices of reeve, deputy reeve and mayor. In religion he was a Presbyterian and in politics a reformer.

Mr. Bertram's wife died about two years ago, the family surviving including four sons and one daughter—Henry, Alexander, Dr. T. B. and James B., of Dundas, and Mrs. Dr. Stirling, of Picton.

From the strenuous activities of his business life Mr. Bertram found time for deep and extensive reading as well as leisure for several trips to his native land. Only a few days before his death as he sat smoking his pipe in his office and growing reminiscent over the changes that had been wrought since his young manhood, he related to the writer an incident on one of these trips which showed the thoroughness of the man. One of hs early undertakings, after learning his trade, was the building and installing of a water wheel, after many weeks of laborious work. Forty years afterwards he visited the mill where the wheel had been placed. He found that it had been running continuously for the operation of the mill during that period, was then running and during all those years had never cost a shilling for repairs.

He dearly loved to delve into the histories and mysteries of earlier civilizations and on the subject of recent archaeological discoveries he was an authority. The Bible also was a feature of his reading, as his intimate knowledge of its contents revealed. Natural science was all absorbing, resulting in a deep insight into several of its branches.

Despite advancing years he kept in close touch with business matters as well as the general affairs of current history, and was keenly alive to the industrial changes and the advances that succeeding years have brought about.

Practical Questions and Answers

Reasons for Compounding Steam Engines.

Ques.—Wherein is the efficiency of an engine increased by compounding?

Ans.—The thermal efficiency of an engine is represented by the formula

$$E = \frac{T - T'}{T}, \text{ where } T =$$

temperature of steam upon entering the cylinder and T' is the temperature of the exhaust steam. It is quite apparent, therefore, that the thermal efficiency of an engine can be increased by increasing the difference between T and T'. The lowness of the temperature of exhaust is limited by the efficiency of condensation. A temperature of about 110 degrees F. is as low as can be obtained with most condensers. Thus T' is limited to 110 degrees F. Thus the tendency for some time has been to raise the boiler pressure and thus the initial temperature T. However, as the difference between T and T' increases the cylinder condensation increases because of the great range of temperature through which the cylinder has to pass. It was to overcome this that compounding was introduced. In the single cylinder the live steam enters, and there is a certain amount of condensation occasioned by the low temperature condition left by the previous exhaust. After cut-off the pressure gradually falls, and as it does the latent heat in the water converts it into steam again under the lowering pressure. At exhaust this steam leaves the cylinder with the rest and is lost.

In the compound engine the expansion and thus the temperature range is divided into two or more parts, each part taking place in a separate cylinder. In the first cylinder the same thing goes on as was described for the single cylinder, except that the ratio of expansion and thus the change in temperature is one-half, one-third or one-fourth as the case may be, but the re-evaporated condensation, together with the rest of the exhaust steam, instead of exhausting into the atmosphere passes into the next cylinder where the heat units are further utilized. In the last cylinder condensation takes place as in the other cylinders, and at exhaust the water is re-evaporated by its latent heat and passes out and is lost in the same way as it is in the single cylinder. However, the amount of condensation is much less in the last of the compound cylinders than in the single cylinder because of the much smaller range of temperatures. Thus the thermal efficiency is increased by compounding because of the decrease in condensation losses.

There is another advantage of compounding which applies only to large units. By increasing the number of cylinders it is possible to distribute the torque, and that is an important consideration in units of large power.

It might be said here that the term "compound" is properly applied to any number of expansions, although it is commonly restricted to a consideration of two expansions, the terms "triple expansion" and "quadruple expansion" being applied to three and four expansions respectively.

* * *

The Efficiency of the Injector.

Ques.—Is the injector an efficient agent for feeding water to steam boilers?

Ans.—Considered from one point of view the injector is a perfectly efficient agent in steam boiler feeding because it has a thermal efficiency of nearly 100 per cent., the small loss being due to radiation. The steam mingles with the water and is condensed, but the entire heat energy of the steam, less the small amount lost in radiation, is carried back to the boiler by the feed water, the heat due to friction in the injector even being reclaimed and carried back to the boiler in the feed water.

But the practical objection to the injector in a good many cases is that the injector can feed only comparatively cold water because the efficient operation of the injector requires that all the steam must be condensed by the water supply, and as the temperature of the water supply is increased the amount required will be increased. In very few injectors is it possible to use a feed-water temperature above 130 degrees F.

This limitation is a decided disadvantage to the injector where exhaust steam might be used to heat the feed water.

* * *

Meaning of Vacuum in Inches of Mercury.

Ques.—What is meant by the expression "a vacuum of so many inches of mercury," and how can it be changed into pounds per square inch absolute?

Ans.—If we take a long glass tube, insert one end in a bowl of mercury, and connect the other end by means of a piece of rubber tubing to an exhaust pump, and partially exhaust the air from the tube, the mercury will rise in the tube until equilibrium is again reached. That column of mercury in the tube is held up by the excess of the atmospheric pressure over the air pressure on the top of the column. Thus it is possible to express the degree of vacuum in the glass tube by the height of the column of mercury held up by the excess of the atmospheric pressure over the absolute pressure in the tube.

To change this expression for a degree of vacuum into pounds per square inch absolute, it will be convenient to take a specific number, say 8 inches of mercury. Then the difference between atmospheric pressure per square inch and absolute pressure per square inch of the vacuum will be the weight of a column of mercury 8 inches high and 1 square inch in cross section, i.e., of 8 cubic inches of mercury. One cubic foot of water weighs 62.35 lbs., and the specific gravity of mercury is 13.58, and thus the weight of 8 cubic inches of mercury is:

$$\frac{8}{1} \times \frac{62.35}{1728} \times \frac{13.58}{1} = 3.9 \text{ lbs.}$$

Atmospheric pressure is 14.7 pounds per square inch absolute, and thus the absolute pressure of the assumed vacuum of 8 inches of mercury is $14.7 - 3.9 = 10.8$ pounds per sq. inch.

* * *

Reason of Boiler Corrosion

Ques.—Do other causes besides mere hardness of the feed water tend to make the metal in contact with the water in boilers corrode?

Ans.—Methods of water purification usually carried on tend to concentrate the solutions of any impurities in the water and cause more corrosion. For instance, a residue of sulphate of soda is usually left in the water. As this becomes more and more concentrated it attacks the boiler and gives trouble at times when the corroding is known to be going on and yet the real cause of it not understood. Again, nitrates and chlorides are even more corrosive than the sulphate. Chloride of magnesia is the worst enemy the metal of a boiler has to contend with when it is present in the water. To avoid corrosion from these causes it is necessary to keep the concentration below the point where the salts will attack iron or steel. Since the water in the boiler will not be uniformly mixed, the concentration is apt to be a maximum where the evaporation is greatest or at a point of greatest heat in the boiler, and these points are likely to be the first attacked. It has been recommended that a boiler be emptied once a week and thoroughly washed every two months in order to avoid the accumulation of these soluble salts.

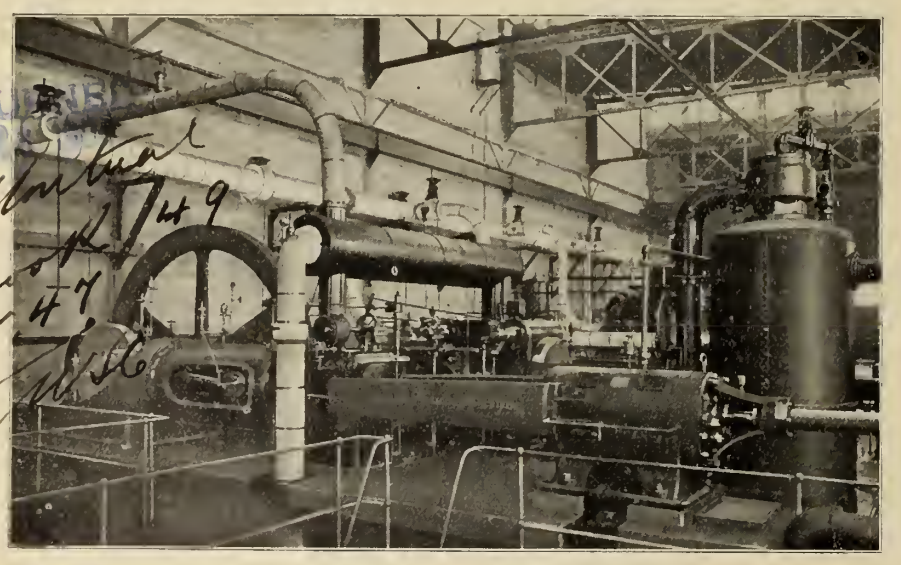
LARGE COMPOUND AIR COMPRESSOR.

A LARGE air compressor in the powerhouse of the Canada Car Co., Limited, Montreal, is illustrated herewith. It is a Corliss cross compound steam and compound air type and was built by Allis-Chalmers-Bullock, Limited, of Montreal.

The compressor is designed to stand a steam pressure of 190 pounds at the throttle of the high pressure cylinder. The steam valve gear is of the standard Corliss release type. The governor is of the improved fly ball type, regulating the valve gear of the steam cylinder and capable of speed adjustment by means of a lever and adjustable weight for at least five revolutions above and below normal speed. The governor is furnished with an air regulator attachment operated by pressure from the air receiver and so controlling the steam cut-offs independently of the action of the governor balls that the speed of the compressor will vary automatically in proportion to the amount of air required.

The air cylinders and heads are thoroughly water jacketed. The air inlet valves are of the Sergeant patent piston inlet type and the discharge valves of the improved poppet pattern. A vertical receiver intercooler stands between the cylinders and is 8 inches in diameter by 13 1-2 feet high, with tinned brass tubes through which the cooling water circulates. It is shown at the right in the illustration. The receiver is situated in the basement beneath.

The steam cylinders are 16 inches and 32 inches in diameter and the air cylinders 18 1-4 and 30 1-4 inches in diameter. The stroke is 30 inches. The view is taken from the high pressure side of the compressor. When operating at 85 r.p.m. the compressor has a piston displacement of [illegible] cubic feet of free air per minute and is designed for a final working pressure of 100 pounds per square inch. Steam is supplied from an adjacent boiler room. The machine is designed to stand a strain of 190 pounds steam pressure

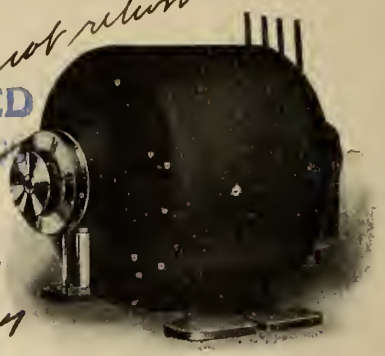


Allis-Chalmers-Bullock Air Compressor in Power House of Canada Car Co., Montreal

with 150 degrees superheat. An idea of the size of the compressor may be gathered from the fly wheel, at the left, which is 12 feet in diameter and weighs 15,000 pounds. The total weight of the compressor is approximately 115,000 pounds.

SMALL POWER MOTORS.

IN the household and industrial field are numerous operations requiring small amounts of power which have usually been laboriously performed by hand, owing to the lack of some convenient and inexpensive driving mechanism. With the growth of the electrical industry and its extension into new lines of work, more attention has been given to the development and perfection of small motors.



Power Motor—Pulley End.

In placing on the market a line of motors which are compact, beautiful and durable the Westinghouse Company feels assured that the results obtained from their use will be most gratifying. For such service as operating sewing machines, dental apparatus, coffee grinders, small ice cream freezers, phonographs, sign flashers, moving window novelties, and hundreds of other adaptations, the smaller sizes may be attached to an ordinary incandescent lamp socket, furnishing a profitable day load for lighting companies.

These motors follow very closely the design of the fan motors described in previous pages—they are built for both alternating and direct-current circuits,

Power Motor—Commutator End

either 115 or 230 volts. The direct-current motors are either shunt or series wound, and the alternating-current motors are wound for 25, 60 or

133 cycles. The efficiency of all machines is exceedingly high.

The base of the motor consists of a separate casting, the frame being drilled and tapped so that the feet may be

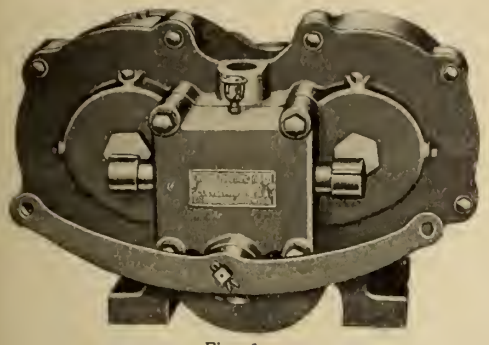


Fig. 1

fastened in any one of four different positions. This construction adapts the motor for mounting in any position. The screw holes in the base are slotted to allow belt adjustment. A two step grooved pulley, suitable for a cord or round belt, is supplied with each motor. The speed abtained by driving from the larger step is about twice that of the smaller.

The bearings are self-oiling and similar in construction to those of the fan motors. They are provided with vertical oil cups with a wick which effectually lubricates the shaft, and a suitable return channel prevents the dripping of oil from the bearings. The leads are brought out through hard rubber bushings, and connection to the motor is easily made. An ordinary lamp cord and plug may be attached to the motor leads for connecting it to an incandescent socket or receptacle. All motors are neatly finished in black enamel with the trimmings of brass, allowing them to be installed where neat appearance is essential. The alternating-current motors are of the single phase induction type with open end frames and split phase winding, the starting coil of which is automatically cut out as the motor comes up to speed. A self-

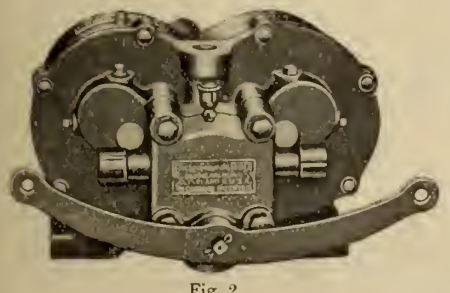

Fig. 2

acting friction clutch engages the load after partial speed has been attained. The direct-current motors are enclosed and are supplied either series or shunt wound, and are so constructed that no starting device is necessary.

THE PNEUMATIC MOTOR.

ILLUSTRATIONS of a pneumatic motor manufactured by the Chicago Pneumatic Tool Co., are given herewith. The pneumatic motor consists of two double oscillating cylinders, set at right angles in an air-tight case. There is no movable valve mechanism, as the oscillation of the cylinders opens and closes the ports. A small quantity of oil is kept in the case, so that the crank in revolving lubricates itself and dashes the oil on the valve seats, from which the air carries it through the inlet ports in sufficient quantities to thoroughly lubricate the pistons. The air ports are controlled by a balanced slide valve, which closes them when on a centre and starts or reverses the motor as it may be turned to the right or left. The valve is thrown by a lever to which chains are attached of proper length to be within easy reach from the floor. When the lever is released the valve is self-closing. The air supply is controlled and the speed of the motor regulated at the will of the operator. The

not returned

APR 25 1906

Westinghouse Small Power Motors

cylinders are bored true, and are automatically adjustable to their valve seats, the adjustment being simple and made from the outside of the motor case. The piston rods are ground. The stuffing boxes are ample and contain sufficient packing for long wear. The cylinder trunnion bearings are bronze. The crank shaft bearings and the crank connections are bronze bushed. The material used throughout is the best obtainable. Superior workmanship is required on all the vital details of construction. Starting Torque of motor is one-half the rated horsepower.

TRACKLESS TROLLEY SYSTEM.

AT Eberswalde in 1901 there was an experimental trackless trolley system installed by a Berlin engineer, but after having been in operation a little over five months it was withdrawn. The length of the Eberswalde line was one kilometer (3,280 feet), running from the railroad station to the centre of the town. For about one-half the distance the road is level and the other half an almost uniform grade of 3 per cent. The roadbed is partly paved with stone blocks and partly macadamized. The electric power, a continuous current from 500 to 550 volts tension, was transmitted on a double line of parallel

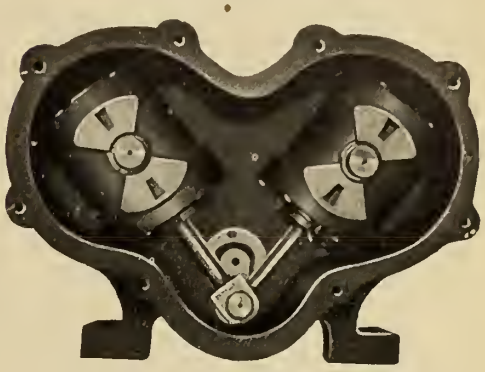

Fig. 3

copper wires 0.315 inch in diameter, 11.8 inches apart, upon which the traveling trolley ran. The latter was equipped with a three-phase motor, which was so adjusted that the trolley always kept at a short distance ahead of the car. The current was received by the wheels of the overhead trolley and transmitted by a flexible cable inclosing six isolated wires—three for the three-phased motor of the trolley, two for the motors of the car, and one for operating an electro-magnetic brake to check the trol-

Fig. 4

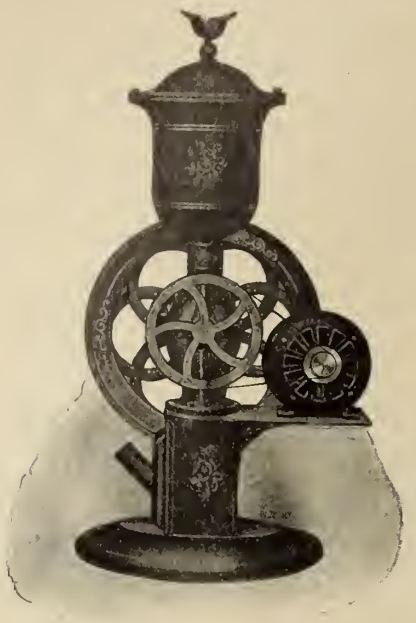
ley in case of necessity, as, for instance, when the car stopped on a grade. The average consumption of current at the central station was 660 watt-hours per kilometer (3,280 feet) per omnibus. The

weight of the omnibus was 3,400 kilograms (7,496 pounds); consumption per ton (2,204.6 pounds) per kilometer, 153 watt-hours; and maximum speed per hour, 14 kilometers (8.7 miles).

Method of Propulsion.

The flexible cable by which the current is transmitted to the motors was connected to an upright or perch on the top of the car by means of a movable sleeve. The tension of the cable was secured by the forward motion of the trolley, but in order to obtain greater elasticity, there was a loop of 4 meters (13.1 feet) put in the cable, which was elongated or shortened by means of a spring and counterweight, the latter working up and down the perch on top of the car. Direction was given to the car by means of a handwheel steering apparatus, acting on the two front wheels of the car, which were pivoted.

An electric motor of eight horsepower was attached to each of the rear wheels. The two motors, however, were capable of producing 25 horsepower for a short time, which was all the power necessary to start the omnibus. Power transmission was by means of chains and cogs. Each car was equipped with change-of-speed and reversing levers.



Power Motor in Operation

The tires used were made of steel. The omnibus was constructed to carry 18 passengers seated, although, if the municipal regulations would permit crowding, there was enough space for double that number.

Cost of Trackless System.

The costs of the installation of the Eberswalde line, owing to unusual conditions, were exceptionally high and can not be regarded as a criterion. The estimated cost of an automobile trolley line of 3.1 miles in length under ordinary circumstances is as follows: Electric line, $9,650; two cars, $6,948; car depot, $2,702; total, $19,300.

The estimated annual cost of operating the above mentioned line on the basis of 30,000 car kilometers annually, the cost of current furnished by the central station being 4.82 1-2 cents per kilowatt, is $1,737. Counting upon receipts of $3,088, or $617.60 per kilometer, the net profit will be $1,351, or 7 per cent. of the capital invested.

The rate charged was 2.38 cents per person. As previously mentioned, the road at Eberswalde was in operation for a little over five months, when, owing to the unusual costs of construction and of operating and keeping the line in

General Outline Drawing of Pneumatic Geared Hoist.

repair, it was withdrawn by the company, although, as the mayor of the town informed me, the line worked to the satisfaction of the municipal authorities. There were some interruptions in the running of the cars, but these were due to the faulty installation of the temporary central power station and not to faults of the system itself. There was also some difficulty experienced with the automatic windlass for keeping a tension on the flexible conductor, causing the trolley to fly off at times.

In conversation with an American engineer, a traction expert and one who is familiar with the conditions existing in cities like Detroit, he expressed the opinion that a petroleum or gasoline motor omnibus would give the most economical results.

Photographs of the car, motors, etc., used at Ebeswalde were furnished by Consul-General Thackara and will be loaned to parties interested upon application to the Bureau of Manufactures.

PRIZES FOR CEMENT DATA.

PRIZES amounting to about $750 are being offered by the Prussian Government and the German Society of Portland Cement Manufacturers, for essays on the processes which take place in the hardening of hydraulic cements. The essays, which take as general subject matter the demonstration of properties and of the induration processes of calcareous hydraulic cements, synthetically, analytically, microscopically and mineralogically as applied to hardening in air, fresh and sea water, may deal with all or any of the following questions:

1. To prove whether silicic acid, alumina and oxide of iron with lime as crystalloids in stable proportions or as colloids in varying proportions.

2. To prove whether double combinations result between silicic acid, alumina and oxide of iron with lime, and in what manner these substances take part in the hardening process.

3. Consideration of the swelling phenomena which accompanies the hydraulic hardening.

4. Consideration of the influence of the temperature and the duration of the burning process on the different kinds of hydraulic cements.

5. Properties of puzzolana and its hardening with lime; beginning with silicic acid, as the most active and prominent puzzolana, alumina, oxide of iron and manganese, independently and in combination with silicic acid, either as natural or artificial puzzolanna. The papers must be written in German and must be submitted under a nom de guerre to the Minister of Public Works, 80 Wilhelmstrasse, Berlin, on or before December 31, 1906.

BOOK REVIEWS

Link Motion. By Fred H. Colvin, sent with the compliments of H. B. Underwood & Co., Philadelphia, New York, the Derry-Collard Co., first edition, 90 pages, illustrated.

This valuable little book deals with link motions, valves and valve settings in a very complete manner, being a subject upon which the author is particularly fitted to express not only an authoritative opinion, but give the benefit of a deep insight into the best practice. The line drawings are clear and easily understood. While the various curved diagrams embody valuable data on the subject.

Injectors: Their Theory, Construction and Working, by W. W. Fullen. Third edition. Manchester: The Technical Publishing Co., Limited, and New York: D. Van Nostrand Co.

This is the third edition of the author's treatise. Since the second edition appeared much experimental work has been done on the steam jet, consequently it has been found necessary to rewrite a good half of the first book, much new matter having been added and many illustrations. In addition to the theory and action of the injector the author goes into detail regarding the mechanism and principles of operation of the various injectors on the market throughout the world. Besides giving the technical side of the question full attention, the author gives considerable space to history and general description. It is of more than passing interest to all those connected with the use of steam boilers.

Notes on Heating and Ventilating, by John R. Allan, Prof. Mechanical Engineering, University of Michigan, Chicago. Published by Domestic Engineering.

In this book various chapters are arranged from a resume of a series of lectures delivered by the author to the classes on heating and ventilating at the University of Michigan and published in a number of articles in Domestic Engineering. One of the main features brought out is the fact of the exact science to which the systems of heating and ventilating have been reduced. The author commences with the theory of heat and measurement of temperature and takes up the different forms of heating systems, their advantages, disadvantages and relative economy. Central heating systems are also given some attention as well as the apparatus required for heating and ventilating. The book is simple and of considerable value to all interested in this line.

Cams, and the Principles of their Construction, by Geo. Jepson, Instructor of Mechnical Drawing, Massachusetts Art School. Cloth bound, 53 pages, illustrated price, $1.50 net. New York: D. Van Nostrand.

On taking up this book, the reader is rather surprised to find the author launching into his subject seemingly in the middle of his work, but a note elsewhere points out that this treatise on cams is to be included in a book on mechanical drawing of which the subject of cams will form a part. The importance of the cam in machinery of various kinds is shown and the method of its adoption to various uses brought out. The author illustrates each step with splendid diagrams and shows exactly how various shapes and mechanisms are drawn out. To the mechanic as well as to the student of mechanical drawing and the mechanical engineer, this book will appeal as giving a practical working knowledge of the subject.

Electric Power Plants, by Norman H. Schneider, electrical engineer. Second edition, cloth bound, 274 pages. New York: Spon & Chamberlain, 123 Liberty street.

In presenting this second edition to the readers the author intimates that it is intended as a hand-book of practical information for those who are called upon to operate a commercial or military electric plant without having had much previous experience, as well as giving valuable information to the engineer. As it was written from notes taken while the author himself was actually handling the apparatus described, it should be practical and to the point. The author leads the reader into the company of the different electrical machinery and apparatus and the conditions met there describing different forms of generators and motors and their care and management, as well as their test and measurement. Besides these some practical notes are given on batteries and belting. While the drawings in this book are clear the engravings are of poor quality.

Machinery Development

Metal Working **Special Apparatus** **Wood Working**

SPECIAL PORTABLE MILLING MACHINE.

H. B. UNDERWOOD & Co., of Philadelphia, have just placed on the market a machine that is a departure from anything yet brought out in the shape of a portable milling machine. This machine is the outgrowth of a temporary rig that we were forced to make to do work on a large machine in a stated time and in place, and from that idea has been elaborated on from time to time until it has become one of our special tools. It is designated for straight line work, 8 feet long, with a number of surfaces in line but on different planes. It being motor driven allows it to be taken to the work, and work of such a character that no machine tool built do as required, for the work can be done after all parts are assembled. The carriage has a travel of 8 feet, with automatic feed; the cross slide has a travel of 12 inches; the vertical spindle a travel up and down of 10 inches. The spindle has a taper hole to receive taper shank mills; the slide on the machine has hand feed. The bed is mounted on a sub base, allowing accurate adjustment by set screws setting up against taper spaces, pieces securely holding the two beds as solid as though in one piece. This sub base has long slots and projections for securing to the work by clamps or bolts.

Underwood Portable Miller

NEW CRESCENT ANGLE BAND SAW

THE cuts of the band saw shown on this page shows a new machine that is a decided innovation from the common type of machines. The machine is designed to overcome the difficulties and inconveniences incident to the tilting-table machines, and on this machine the table is always level whether doing square or angle sawing, regardless of the angle being cut. This is accomplished by tilting the arm upon which the upper wheel is mounted to the desired angle. This arm is hinged into the pedestal in a very rigid manner, making the machine as rigid and durable as any of the common type of machines. The method employed in hinging the arm is very similar to the method of mounting the table of a common drill press to its column and in comparison is as rigid. The only operation necessary to change angle of cut is to turn hand wheel at side of table until index under table points to desired angle on the graduated quadrant. The guides keep proper alignment with saw without attention. There are no sliding throat-blocks to push into position, as the table travels automatically to keep saw in proper register in the saw slot. The one operation of turning the hand wheel takes care of all the adjustable parts of the tilting mechanism, and if desired the machine may be tilted while the saw is cutting. This feature adapts the machine for boat work or other similar work. The arm is suitably counterbalanced so hand wheel turns easily. Extreme simplicity is also claimed for the machine, there being but a few more parts used than on the common type of band saw made by the same manufacturers. The novel features of the machine are covered by patents recently issued.

The machine has already had an extensive sale, and the manufacturers report that they have plans under way for enlarging their factory to accommodate their increasing business. A postal card addressed to the Crescent Machine Co., Leetonia, Ohio, will bring a copy of their new catalogue in which the machine is more fully described.

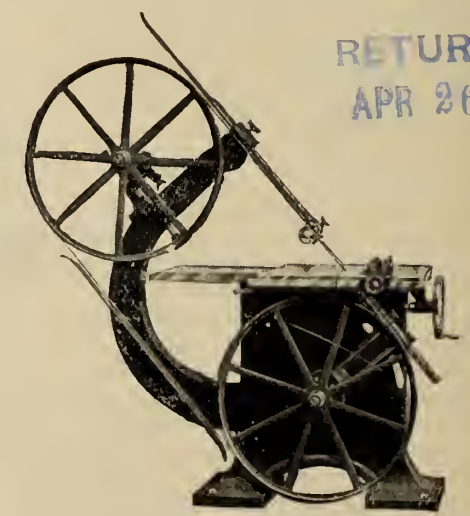
CHAIN MAKING BY MACHINERY

ONE of the last industries to be invaded by the all-conquering machine is that of chain making. The manufacture of chains, which in England has had its seat in Cradley Heath and the neighboring villages for certainly over a cen-



RETURNED
APR 26 1906

Fig. 2—The Crescent Angle Band Saw Tilted for Bevel Sawing

tury, has held out for long against the falling into line of modern economy and the supersession of the old hand process by labor-saving machinery.

The old process of chain making was the anvil one, indeed still is, because, although chain making machinery is being introduced, conservatism dies hard, and the methods of our grandfathers are far from extinct. Under this old process the iron was cut into short lengths, each sufficient to make one link. After being heated in the furnace once, the bar was bent into a U-shape; after a second heating the two ends were tapered down, and after a third heating the link was welded on the horn of the anvil, the whole operation being performed with a hand hammer. An expert chain smith at such work might turn out, perhaps, 40 ft. of ¾ in. coil chain per day, but could scarcely do more.

Under the new machinery output has been multiplied by four, and the quality is not inferior. One heavy machine—called the link-winding machine—coils the round iron bar of any thickness within the compass of the machine's power around a mandril without heating. The mere fact of the iron being wound cold ensures a certain standard of quality, as poor iron would not stand the process. The result of the coil-winding is that the bar issues in the form of a close spiral spring, the circle of each coil containing a sufficient length of iron for one link. The size of the mandril used is, of course, suited to the chain which is in process of manufacture. The next process is that these coiled bars are subjected to the link-cutting machine, which also operates upon the iron in a cold state. Each coil is cut off at an angle of 60 deg. from the face of the flat section, this form being best suited for the subsequent welding. The welding machine is the last, and not the least, ingenious of the three called into requisition in the modern process of chain making. It is really a spring hammer driven by power, and controlled by a foot lever. When the foot lever is not depressed, the hammer is raised clear from the anvil or bed. Thus there is always space to allow the chain to be placed in position or withdrawn. The depression of the controlling foot lever brings the hammer into action, and blow succeeds blow, until the operator, believing the welding to be satisfactory, releases the lever, and the hammer rests ready to descend for the next link. This operation is, of course, performed with the half-formed links heated to a welding heat. The hammer and the anvil are fitted with steel dies or molds suited to the shape of the link being manufactured. These dies are easily removable, so that different sizes of chain may be made on the same welding machine. Before putting the link to be formed under the hammer it is hooked into the link last formed, and thus the chain is built up.

CONTINUOUS FEED GLUE JOINTER

A MACHINE that can be used on long or short stock with equal success and will make a clean cut joint, is a recent product of the works of Cowan & Co., Galt.

The frame is cast in one piece and is of rigid design, thereby avoiding twisting and straining when doing rapid work. The chain is composed of forty-four links all milled accurately to fit

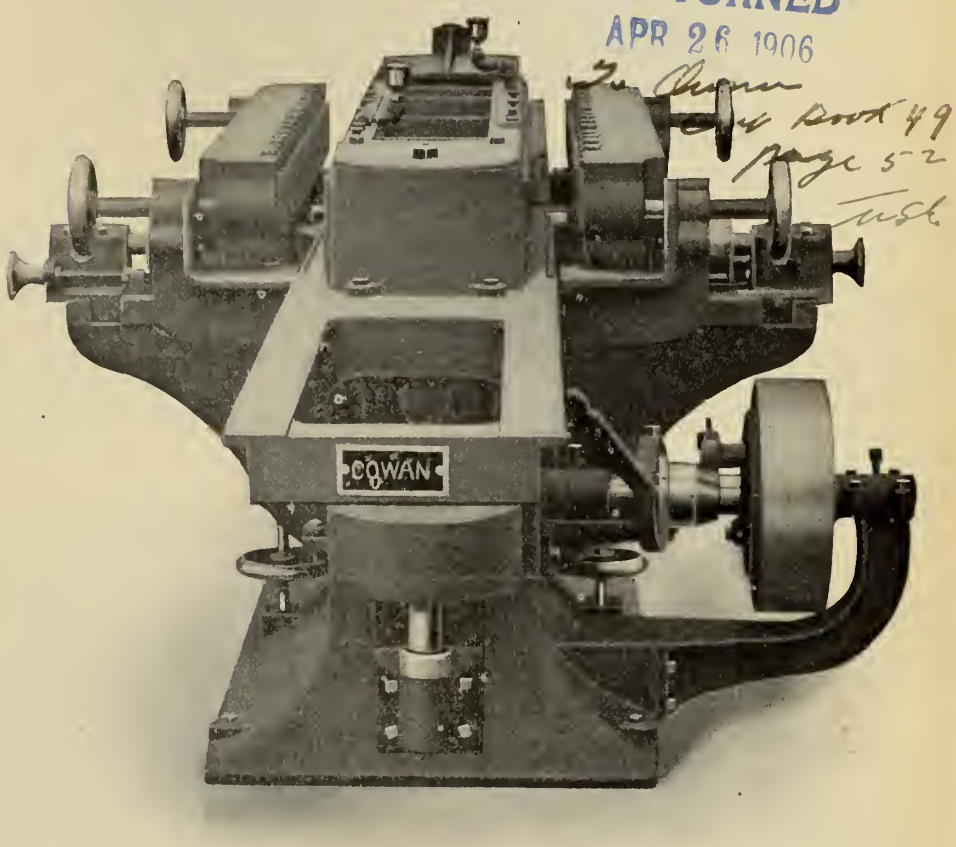
Book 49
page 5-2



Cowan Continuous Feed Glue Jointer.

cams so as to ensure a smooth running motion, and corrugated to ensure stock passing through without slipping. The pressure bars are each provided with twelve 2 inch by 2 inch knurled steel rollers which operate upon tempered springs. Variations of 1-4 inch or 3-8 inch in stock does not make it necessary to change bars, as springs take care of this. Bars are adjusted by hand wheels on either end of bar, and adjustments can be made in an instant. The arbors are made of special high carbon steel of large diameter, and run in self-oiling bearings. They have vertical and lateral adjustment. They are fitted with any kind of solid cutters desired for either tongue or groove or straight-faced joints. The feed is controlled by friction pulley which drives the gears and can be started or stopped instantly by throwing lever. It is geared six to one, and has three rates of feed, 45, 57 and 68 lineal feet per minute, about four times the capacity of ordinary machines. Will take stock from 6 inches up to any length and from the thinnest to 2 1-4 inches thick. The gears are made of steel and after the most approved methods, ensuring long life and a smooth running machine. Countershafts are provided and machine can be belted from below as well as from above. Fast and loose pulleys 12 in. diameter, 6 in. face, and should make 900 revolutions per minute. Drive pulley 22 in. diameter, 4 in. face; arbor pulley 4 in. diameter, 4 1-2 in. face, and should make 5,000 revolutions per minute. Floor space required 13 feet 6 in. by 3 feet 8 in. for 6 foot machine.

VICTOR PIPE MACHINE.

RATHER antagonistic qualities, strength and lightness are desirable in a pipe threading machine. The pipe machine illustrated as manufactured by the Loew Manufacturing Co., Cleveland, Ohio, embodies these two features. It is solidly constructed.

being designed to resist rough usage and as may be seen from the engraving, occupies a comparatively small space. Power is transmitted by a double-lead worm gear, set close to the base of the machine, the worm gear having been found to be more powerful than bevel gears, and by using a double-lead worm gear the speed maintained is the same as if bevel gears were used.

Jardine Bolt Machine—Hand Drive

Another important feature in connection with the dies is that during the operation of cutting the thread the pressure of the pipe against them prevents all danger of their slipping. Usually it is necessay to employ some device to lock the head, to prevent the die from slipping after the threading begins. No levers or locking devices used on the head, and there are no projections on the face plate. The face plate adjusts the dies, which engage in a continuous scroll on the back of the plate. The plate is self-locking, requiring no bolts to lock the dies when adjusted to the desired size. Each machine is supplied with an oil can and a tripod for supporting.

The vise is a universal, self-centreing vise, with two long bearing jaws made of tool steel. The pipe is clamped in the vise by a hand wheel which is large enough to insure the pipe being held perfectly rigid in the jaws when set. To assist in setting the dies there are gradnations on the face plate. The dies are set by inserting a small hand bar on the edge of the face plate, shifting it backward and forward as necessary. When the pipe is placed in the machine and the size has been adjusted and the vise jaws clamped, the operation is started by drawing the hand lever toward the front of the machine and revolving the the head by means of the hand crank. After the pipe is started into the dies it continues to feed itself automatically. After the thread has been cut the dies are released by inserting the bar into one of the holes in the edge of the face plate and opening it slowly. This takes off the burrs of the thread. The quick opening feature obviates the necessity of reversing the machine and backing the pipe out of the dies.

Jardine Bolt Machine—Power Drive

SHORT HISTORY OF AN IMPORTANT TOOL.

WHEN the last century came in the steel square used by every carpenter had never been made. The inventor of this square was Silas Howes, who lived in South Shaftsbury, Vt. One day, according to Modern Machinery, Silas was visited by a peddler who called to have a shoe set on his horses. These peddlers were given to excessive barter and exchange. This one had some worn-out steel saws and then and there Silas received the inspiration to make a square. He shoed the horse and was paid in old

saws. Silas proposed to weld and polish the saws and make a rule superior to anything in use. He succeeded and marked it off into fractions of inches and found it good for the purpose. At first he made them at odd times and sent them out by the peddler, who found every handy man and carpenter eager to possess one at $5 and $6. The orders exceeded the supply and Silas applied for and obtained a patent for the invention. Gradually he worked up enough business to build a factory, which was the beginning of a large industry. Silas Howes became a very rich man and was a generous one. Squares are now being made on the site where the first one was manufactured ninety-five years ago.

125 TONS OF METAL IN A SINGLE CASTING.

PATTERNS for what will be the heaviest single casting ever poured at the works of the Allis-Chalmers Co., Milwaukee, were completed recently in the pattern shops of the West Allis works. The casting in question is designed for the frame and slide of a large horizontal rolling mill engine being built for the Carnegie Steel Co., Sharon, Pa., whose cylinders will be 50 and 78 inches diameter with a 60-inch stroke. The pattern for this piece, measuring 2 feet long, 11 feet wide and 10 feet high, represents the work of ten expert pattern makers for a period of four months. The amount of lumber of various sizes used in its making aggregated 22,000 feet. The pattern was taken from the pattern shop directly to the foundry where work has begun on the construction of the mold. The pit in which the piece will be poured is 40 feet long, 15 feet wide and 11 feet deep. The mold, when completed and ready to receive the molten metal, will take approximately 133 tons of iron; the actual operation of pouring will consume some eight to ten minutes. Nine ladles will be used to convey the liquid metal to the mold, four of which will each be of five tons capacity, four of 25 tons and one of 13 tons. After the metal is poured, the casting will be allowed to stand and cool for six days before the mold will be broken.

Two of the largest traveling cranes will be required to lift the casting, the aggregate weight of which will approximate 125 tons. It is expected that the finished piece will be ready for shipment in from seven to eight months' time, when one of the new sixteen wheel 100-ton flat cars, now being built for the Allis-Chalmers Co. at the West Milwaukee shops of the Chicago, Milwaukee & St. Paul railway, will convey the piece to Sharon, its final destination.

At the Noon Hour

Ought to be Satisfactory.

"I suppose," said the fair customer, "you guarantee these corsets?"

"Certainly, madam," replied the absent-minded clerk, who had formerly traveled for a boiler foundry. "We warrant them to stand a pressure of 700 pounds."

* * *

The Overworked Boiler.

"Are you chief engineer of this concern?" asked an excited individual of the sub-editor.

"No, sir, I'm not the engineer; I'm the boiler," and he proceeded to "boil down" six sheets of matter into a note of six lines.—Tit-Bits.

* * *

Father Knew.

"Pop."

"What is it, Johnny?"

"Why is the head of a bedstead always higher than the foot?"

"For the same reason that the rear wheels of a wagon are always bigger than the front ones, Johnny."

"Thanks, pop."—Kansas City Times.

* * *

No Work for Him.

Housekeeper: "You're a big, healthy man; why don't you go to work?"

Tramp: "Lady, I'll tell yer me trouble. I'm an 'unhappy medium.'"

"What do you mean by that?"

"Well, yer see, I'm too heavy for light work, an' too light for heavy work."—Pearson's Weekly.

* * *

She Swore Off.

An old lady who was in the habit of saying after any event that she had foretold it was one day "sold" by her husband, who had got tired of her eternal "I told you so!"

Rushing into the house, he dropped into a chair, raised his hands, and exclaimed: "Oh, my dear, what do you think? The old cow has gone and eaten the grindstone!"

"I told you so! I told you so!" was the reply. "You always let is stand out of doors."

* * *

The Attainment of an Ideal.

We have all of us an ideal—all of us,, that is to say, who are likely to be worth anything, and the only difficulty about the matter is that not one per cent. of us ever attain it.

The reason is not far to seek, for the inability to reach the limit of our desires is caused by our failing to grasp the utmost possibilities of our present position. It is no good for a clerk on thirty shillings a week to wish to become a millionaire unless he can extract all the possible good out of his present limited income.

The very meanest position, the very humblest office has its own ideals, and unless the man in the mean position has found the fullest capabilities of his lot, he will never get much higher on the ladder of success.

To put this more plainly, there are many ways of living through every walk of life, and it is your duty, if you would get on, to find out the best way of living your own particular life.

If you are an apprentice at present, the moment you have realized the full possibilities of your apprenticeship you are ready in every way to go in for something better. If, on the other hand, you have not made yourself acquainted with those possibilities, there is not the least use in the world for you to sigh for things you will never be able to possess. Plant your foot firmly on the rung of life's ladder upon which you now stand, and it will not be long before you will find you are standing on the next one.

* * *

A Pie Machine.

One man and three boys, with the aid of a machine, can make 16 pies a minute. The machine is 10 feet long and 20 feet wide. An electric motor furnishes power and a gas jet keeps the dies warm. Observing the working process of the machine does not dispel the Yankee appetite for pie, but a description of it beginning with the tank suspended over the machine holding "filling" for 400 pies with a revolving agitator to keep the stuff from blocking the outlet would tend to reduce the search at lunch counters for "pies that mother used to make."—Ex.

* * *

In Olden Times.

"There goes Rome's celebrated lightning calculator," says Quintus Flaccus to Casca Smith, who is spending a few days in the capital city.

"Who do you mean—that high-browed man going down the Appian way?"

"Yes. That is Numerous Speedibus. It was day before yesterday that he gave a public exhibition, and one of his amazing feats was the multiplication of MDCCCLXXXVIII by MMCCCXXXIXX in forty-two minutes by the elepsidra."—Ex.

ABOUT CATALOGUES

By mentioning Canadian Machinery to show that you are in the trade, a copy of any of these catalogues will be sent by the firm whose address is given.

Sur-Coat. A catalogue of the Sur-Coat Mfg. Co., Windsor, Ont., describing the merit of sur-coat for removing scale from boilers. It contains many testimonial letters. Size, 5 1-2 x 6.

Grooved Shank Chucks. A folder issued by Baines & Peckover, Bay street, Toronto, of the grain grooved shank chuck for drills, reamers, taps, etc., and describing the grooved system. 3 1-2 x 6 1-4.

Equipment of Modern Ship Yard. A 16-page bulletin, splendidly illustrated, describing the electric equipment of a modern shipyard, showing the adaptation of the Bullock motor to various machine tools. Size, 8 x 10 1-2.

Clutchology. Describes the automatic clutch manufactured by the Automatic Clutch Co., Akron, Ohio, the motto being "The greater the load the tighter the grip," and self-adjusting. 16 pages, 3 1-2 x 6 1-4.

The Interpole Motor. Circular No. 25, issued by the Electro Dynamic Co., Bayonne, N.J., gives a short description of the interpole motor and a number of illustrations showing the wide range of application. Size, 6 x 9.

Electric Motors and Dynamos. Bulletin D issued by the Maple Leaf Automobile Electric & Mfg. Co., London, Canada, shows the different lines manufactured by this company, together with some testimonials telling of their success.

The Rise of a Great Company. An 8-page folder issued by the Allis-Chalmers Co., shows the progress made by that company in recent years. Illustrations of the various plants are given and a general survey of the lines turned out.

Gas Producing Apparatus. C. M. Kemp Mfg. Co., Baltimore, Md., are sending out their catalogue of the Twentieth Century gas producing apparatus supplied by them. The process for producing gas is described and illustrated. 22 pages, 6 x 9.

Marine Motors. Buffalo motors manufactured by the Buffalo Gasoline Motor Co., of Buffalo, N.Y., are fully described in this catalogue, which contains many illustrations of the different lines. These are all used for marine purposes. 32 pages, 6 x 9.

The Defiance. An 8-page folder issued by the Defiance Iron Works Co., Limited, Chatham, Ont., describing their marine stationary and portable gas and gasoline engines and launches as manufactured by them and being placed on the Canadian market with considerable success.

Blue Book of Rope Transmission. The 4th dition of the catalogue published by the American Mfg. Co., 65 Wall street, New York. It shows the advantages of rope drives and their adaptability to different commercial problems. It is well printed and handsomely illustrated. 58 pages, 6 x 8.

Westinghouse Fan Motors. A beautiful catalogue issued from the publishing department of the Westinghouse Electric & Mfg. Co., Pittsburg. The fans being placed on the market by them for 1906 are therein illustrated. In addition a number of pages are devoted to small power motors for both direct and alternating current. Nineteen pages, 6 x 9.

Power Gas Plants. A reprint from the Practical Engineer of a paper by Thos. Rigby, on power gas plants and some of their uses. It goes into the subject in a thorough manner from a technical and practical standpoint. Reports of some actual tests are given that show the operation of these gas plants. 63 pages, 5 x 7 1-4.

Hoisting Machinery. A descriptive catalogue of the Harris patent power hoisting and carrying machine, manufactured by C. S. Harris Co., Rome, N.Y. It describes the machine and its special features as well as giving instructions for installing, together with a number of illustrations showing its adaptation. 24 pages, 6 x 9.

Turbines and Centrifugal Pumps. Catalogue just issued by I. P. Morris Co., Philadelphia, the mechanical engineering Co., of the Wm. Cramp & Sons' Ship and Engine Building. It illustrates the enormous turbine built by this company. Shawinigin Water & Power Co. shows curves of tests on this and other large units. 10 pages, 8 1-2 x 10 1-2.

Crossley's Gas Engine. The English makers of gas engines have begun to notice the normous field for their output in Canada. The catalogue in question describes the admirable points of the Crossley Bros., Limited, gas and oil engine manufactured at Openshaw, Manchester. These engines are substantially built and of attractive design. Size, 5 1-2 x 8 3-4.

Loomis-Pettibone Gas Generating Plants are attractively described by means of diagrams and colored plates in a new pamphlet that is being issued by the Power & Mining Machinery Co., Milwaukee, Wisconsin. This system gasifies bituminous coal, wood, charcoal, lignite, etc., and produces a gas that is particularly adapted to the operation of gas engines. The water gas made by this system can be used separately in various feeding work, such as forging, welding, tempering, etc. This pamphlet can be had upon application to the company.

Machinery and Tools. The 1906 catalogue of Brown & Sharpe Mfg. Co., Providence, R.I., has recently been issued. Any who have in previous years received this catalogue know its completeness and value, containing as it does not only illustrations and descriptions of the various lines manufactured by Brown & Sharpe, but, as well, many pages of valuable data and tables for the machinists and manufacturer. Anyone desiring one of these catalogues will receive same by dropping a post card to Brown & Sharpe, mentioning this paper.

Horizontal Engines. Bulletin No. 137 has just been issued by the B. F. Sturtevant Co., of Boston, Mass., in its engineering series. It very fully illustrates this series of engines, ranging from 20 to 200 H.P. capacity, which has recently been entirely redesigned. All engines are now completely enclosed, provided with watersheded partitions and equipped with forced librication. Although primarily designed for direct connected driving of Sturtevant generators, these engines are peculiarly adapted for all classes of work where high speed, efficiency and perfect regulation are desired. The positive system of forced lubrication relieves the engineer of anxiety and insures continuous operation with the minimum of care.

SOMETHING OR NOTHING

Every man who can be a first-rare something—as every man can be who is a man at all—has no right to be a fifth-rate something; for a fifth-rate something is no better than a first-rate nothing.—J. G. Holland.

* * *

Every great reform which has been effected has consisted, not in doing something new, but in undoing something old—Buckle.

ENGINEERING NEWS

AND SOCIETY NOTES

SOCIETY OFFICERS.

Canadian Mining Institute.

President, George R. Smith, Thetford Mines, Quebec; secretary, H. Mortimer Lamb, Victoria, B.C.; treasurer, J. Stevenson Brown, Montreal.

Toronto Branch A. I. E. E.

Chairman, H. A. Moore; vice-chairman, R. G. Black; secretary, R. T. McKeen.

Marine Engineers.

Grand president, E. J. Henning, Toronto; grand secretary, Neil J. Morrison, St. John, N.B.

Canadian Electrical Association.

President, A. A. Wright, M.P., Renfrew, Ont; vice-presidents, R. G. Black, Toronto, John Murphy, Ottawa; secretary-treasurer, C. H. Mortimer, Confederation Life Building, Toronto.

Canadian Association of Stationary Engineers.

President, Wm. A. Sweet, Hamilton: vice-president, Jos. Ironsides; secretary, Wm. Outhwaite, Toronto; conductor, Ed. Grandbois, Chatham; doorkeeper, Chas. Kelly, Chatham.

Ontario Association of Stationary Engineers.

President, Geo. Fowler, Toronto; vice-president, W. F. Chapman, Brockville; treasurer, Charles Moseley, Toronto; registrar, W. G. Blackgrove, Toronto.

Canadian Railway Club.

President, S. King; secretary, James Powell, chief draughtsman motive power department, G. T. R. treasurer, S. S. Underwood, chief draughtsman car department, G. T. R.

Engineers' Club of Toronto.

President, F. L. Sommerville; treasurer, W. J. Bowers; secretary, Willis Chipman, Rooms 96 King St. W.

Canadian Society of Civil Engineers.

President, H. D. Lumsden, Ottawa; vice-presidents, M. J. Butler, Ottawa; C. B. Smith, Toronto; W. M. Walbank, Montreal; secretary-treasurer, not yet appointed. Rooms, 877 Dorchester street, Montreal.

Society of Chemical Industry

Chairman, Prof. W. H. Ellis; vice-chairmen, H. H. Van Der Linde, Milton; H. Hersey, A. McGill; hon.-secy., Alfred Burton, 11 York Street, Toronto.

Ontario Land Surveyors.

President, Otto J. Klotz, Ottawa; vice-pres., Thos. Fawcett, Niagara Falls; secy.-treas., Capt. Killaly Gamble, Toronto.

Engineers' Society, S.P.S., Toronto University.

President, K. A. McKenzie; vice-pres., B. J. McGugan, rec. secy., A. M. Damn; treas., G. E. Quance; cor. secy., A. E. Jupp.

Civil Engineers' Meetings.

At meetings of the mechanical and general section of the Canadian Society of Civil Engineers, held at their rooms in Dorchester street, Montreal, papers of considerable interest have been read. Amongst these were "Notes on the Shops and Power House of the Canada Car Co.," by E. G. M. Cape; "Durability of Wire Rope Under Severe Conditions," by P. H. Schwitzer; "Formulae for Reinforced Concrete Beams," by Henry Goldmarch. These papers were all illustrated by lantern slides.

Toronto Engineers' Club.

When the Engineesr' Club of Toronto met at their rooms during the month of April, a wide range of subjects was described and discussed. The first meeting resolved itself into a discussion of the city plan of improvements. At the other meetings the following papers were read and discussed: "The Hillsborough Bridge," by M. J. Haney; "Turbine Pumps," by W. C. Brown, Montreal; "Electric Smelting of Iron Ore," by J. W. Evans.

Society of Chemical Industry

The Canadian section of the Society of Chemical Industry held its annual meeting in the Engineers' Club Room, Toronto, on April 6. The proceedings opened with a dinner at 6 p.m., with the president, Dr. F. J. Smale, in the chair. The following officers were elected for the ensuing year: Chairman, Prof. W. H. Ellis, of Toronto; vice-chairmen, H. Van Der Linde of Toronto, Milton H. Hersey of Toronto, A. McGill of Ottawa; committee, James H. Bowman of London, W. R. Lang, J. P. Murray, Charles Heys, W. H. Van Winckel, W. Lash Miller, Prof. W. P. Cohoe and Dr. F. J. Smale, all of Toronto, Prof. M. A. Parker of Winnipeg, Prof. R. F. Rattan of Montreal, and E. B. Chadsey of Hamilton; honorary local treasurer, J. W. Bain; honorary local secretary, Alfred Burton.

A paper was read by Prof. W. R. Lang, of the University of Toronto, on "The Determination of Boric Acid," the result of joint investigation by the author and Mr. R. J. Manning, of the University of Toronto. The methods devised by these gentlemen gave much more accurate results and, therefore, more valuable in connection with the estimation of the percentage in food stuffs than any methods heretofore in use. Following this was a paper, "A Talk on Foundry Chemistry," by H. L. Bowers, B.S., which was followed by an interesting discussion.

In view of the importance of this society from the fact of its influence in other countries there has not been as much progress made as should be expected. This is probably due to the fact that people have not realized to what an extent all manufacture is indebted to chemistry, the result being that a few enthusiasts are left to work up this field while every manufacturer in the country should be personally interested. The presidents of the parent society in England have been among the most prominent scientists of the country.

Amendments to Stationary Engineers' Act.

At a meeting of the executive of the Canadian Manufacturers' Association a resolution was adopted in favor of the proposed amendment in the act regarding stationary engineers under consideration at the present session. The plea of the engineers is a just one and it is satisfactory to note its favorable consideration at the hands of the Legislature. The following clauses are included:

It shall be unlawful for any person to operate any boiler of 50 horse-power or over unless he has a certificate granted under the provisions of this act;

It shall be unlawful for any person to employ an engineer to take charge of a boiler of 50 horse-power or over unless such person holds a certificate under the provisions of the act, and any person who shall be guilty of operating, or any employer who shall employ any person to operate, a boiler contrary to this act, shall be deemed to have committed a misdemeanor;

Every engineer who shall be in charge of any steam plant coming under the provisions of this act at the time it comes into force or any engineer who has had two years' experience and who applies before the expiry of one year, shall, upon proving his character and upon paying the prescribed fee, receive a certificate for the term of two years, and such certificate must be renewed from time to time as it expires, provided, however, the board shall have power to revoke any certificate upon proof of incapacity, drunkenness, or improper conduct;

Any person who feels himself aggrieved by the decision of the board of examiners shall have the right (upon notice being given to that effect) to appeal to the Minister of Agriculture;

All candidates for certificates, except as provided for in section 4, shall furnish evidence of their good character, and of having at least three years' experience, either as assistants in an engine room, or boiler room, or as having full charge, and shall submit to such examination, written or oral, as the board may determine;

All certificates shall at all times be exposed to view in some conspicuous place in the boiler or engine room, and the failure to expose same will be prima facie evidence of the lack of qualifications under the act.

ELECTRIC POWER FOR ONTARIO.

(Continued from page 177)

tion adopted is that of steel towers and first-class cedar pole construction.

Cost to Municipalities.

For Hamilton and Dundas, with 16,000 h.p. estimated requirements, the cost per h.p. is taken at $15.36 a year; for 8,000 h.p. at $16.30.

Toronto, 50,250 h.p., $16.53; 25,125 h.p., $17.15.

Orangeville, for full load estimated, $23.66; half load, $30.54.

Brampton, $21.23 and $25.37.

Georgetown, $20.14 and $23.70.

Milton, $19.80 and $22.40.

St. Mary's, $25.86 and $34.20.

Stratford, $20.48 and $24.04.

Tavistock, $23.50 and $29.12.

New Hamburg, $22.34 and $26.08.

Baden, $23.91 and $28.06.

Berlin and Waterloo, $17.36 and $19.27.

Guelph, $18.39 and $20.95.

Hespeler, $18.48 and $20.58.

Preston, $17.99 and $19.76.

Galt, $17.35 and $19.13.

Brantford, $16.87 and $18.47.

St. George, $17.14 and $18.62.

St. Thomas, $21.89 and $27.21.

London, $19.51 and $23.03.

Tillsonburg, $24.30 and $31.86.

Ingersoll, $18.81 and $21.93.

Woodstock, $18.26 and $21.11.

Paris, $18.12 and $20.50.

Windsor and Walkerville, $27.13 and $35.47.

Wallaceburg, $30.74 and $42.02.

Dresden, $30.87 and $40.79.

Chatham, $24.62 and $30.15.

Thamesville, $27.83 and $34.43.

Bothwell, $25.45 and $31.11.

Glencoe, $27.04 and $32.90.

Sarnia, $29.28 and $39.91.

Petrolea, $25.52 and $32.47.

Oil Springs, $26. and $33.28.

Alvinston, $27.64 and $34.19.

Strathroy, $27.82 and $36.83.

Capital Required.

The capital cost is estimated in detail for a generating plant at Niagara, including tunnel tail-race, $1,250,000; headworks and canal, wheelpit, power house, hydraulic equipment, electric equipment, transformer station and equipment, office building and machine shop, miscellaneous items, engineering and contingencies and interest, a grand total for twenty-four-hour power of 50,000 h.p. development of $5,786,500; for 75,000 h.p. of $7,019,584, and for 100,000 h.p., $8,631,168. The capital cost per h.p. is, thus, for 50,000 h.p. development, $116; 75,000 h.p., $94; 100,000 h.p., $86. The estimate is based on the best class of construction, the machinery to be of 10,000 h.p. units with one spare machine in each case.

Companies Incorporated

The Yucitan Power Company, Limited, capital stock of $1,000,000, for the purpose of constructing and operating power plants of all kinds. Directors are J. S. Lovell, W. Bain, R. Gowans, S. G. Crawell, J. H. Castles.

The Moffatt Fuel Saver, Limited, has been incorporated under Dominion charter, to carry out and transact all matters comprised in the company's charter of earlier date. N. J. Kerr, civil engineer, of Ottawa, to be its attorney.

The Evans Co., Limited, has been incorporated with a share capital of $100,000, with head office at Sudbury, Ont., to carry on a lumbering and contracting business. The directors are Wm. A. Evans, F. H. Aurie and D. H. Andrees.

The Canadian Athinite Co., Limited, has been incorporated with capital stock of $300,000, with head offices at Toronto, to develop chemical processes under letters patent. Directors are J. S. Lovell, William Bain and Robt. Gowans.

The Hussey Construction Co., Limited, has been incorporated under Dominion charter; total capital stock of $20,000, for the purpose of carrying on a construction business. Directors: H. R. Hussey, W. H. Whitehead, G. E. Hussey, A. Curville and P. Surveyor.

Huron Oil Producers, Limited, has been incorporated with a capital stock of $60,000, to carry on mining operations in connection with oil and gas. The directors of the company are W. McIntosh, J. Brahaney, G. E. Corell; J. A. McIntosh and D. Urquhart, with head office at Petrolea, Ont.

The Chatham Motor Car Co., Limited, has been incorporated with a capital stock of $50,000, to manufacture and deal in gasoline engines and automobiles, with head office at city of Chatham. The directors of the company are R. J. Gardner, R. L. Brackin, P. Dillon, T. K. Helmes and W. J. Taylor.

The Brussels Oil Co. have been incorporated under Ontario charter with a share capital of $100,000, for the purpose of dealing in petroleum oil, natural gas, etc., and sink wells for same. The provisional directors are David Ross, W. L. Holmes, H. L. Jackson and W. M. Sinclair, with head office at Bussels, Ont.

The J. B. Abel & Fils Co., Limited, has been incorporated under Dominion charter; capital stock of $20,000, for the purpose of manufacturing boxes, doors, sashes, furniture, and the manufacture of lumber for trading. The directors are J. O. Ogbott, J. B. Abel, A. Desnoyers, M. Ebhet. Chief place of business, Montreal.

The Federal Colonization & Land Reclaiming Co. has been incorporated under Dominion charter with a capital stock of $500,000, to carry on the business of land reclaiming and improvement. The provisional directors are J. R. Booth, W. Anderson, A. A. Taillon, D. M Finnie, J. W. Hennsey. Chief place of business, Ottawa.

The British & French Motor Car Co., Limited, has been incorporated with capital stock of $50,000, for the purpose of manufacturing and dealing in bicycles, automobiles and motor boats, with head offices at the city of Toronto. The directors of the company are J. C. Palmer, E. E. Palmer, H. N. Baird, E. T. Malone and A. Hearns.

The International Gold Dredging Co. has been incorporated under a Dominion charter with a capital stock of $1,000,000, for the purpose of carrying on mining operations and contract engineering work. The provisional directors are W. H. Roughsedge; R. V. Sinclair, C. M. Farley, A. McFarlane, with chief place of business at Ottawa.

John Millen & Co. have been incorporated under Dominion charter with a capital stock of $100,000 for the purpose of carrying on a wholesale and retail hardware and hardware sundries business. The provisional directors are John Millen, John E. Millen, Wm. Strachan, G. R. Lighthall and F. W. Sharp, with chief place of business at Montreal.

The Mann Brass Manufacturing Co. have been incorporated under Ontario charter, with a share capital of $50,000, for the purpose of manufacturing and dealing in brass goods and plumbing supplies. The provisional directors are Andrew W. Mann, Lila Mann, Charles Dunn, John Howard, Wm. O'Brien and Frederick Higman, with head office at London.

Alphaduct Mfg. Co., Limited, has been incorporated under Ontario Provincial charter, with a capital stock of $40,000, to carry on the business of manufacturing and dealing in electric conduits, and to take over the business now being carried on. Directors of the company are F. B. Johnson, C. W. Bongard and S. Johnson. Head office at Toronto.

Northwestern Brass Co. have been incorporated under Dominion charter with a capital stock of $100,000, for the purpose of manufacturing and dealing in brass castings, railway and foundry supplies, etc. The provisional directors are J. T. Ostell, Peers Davidson, A. Wainwright, F. H. Hewitt and Thornton Davidson, with chief place of business at Montreal.

The Delhi Light & Power Co., Limited, has been incorporated under Ontario Provincial charter, capital stock of $40,000, for the purpose of constructing and operating work for the production, distribution and sale of electricity and gas. The directors are Peter Quance, S. Stroup and R. Quance; G. G. Byers and E. Morgan, of the village of Delhi, Ont.

Jones Underfeed Stoker Co. has been incorporated under Dominion charter with a capital stock of $150,000 for the purpose of manufacturing and dealing in stokers, furnaces, boilers, etc. The provisional directors are C. E. A. Goldman, J. McD. Miller, T. A. Silverthorn, B. A. C. Craig, D. A. Brebner, T. G. McConkey, and A. W. Holmstead, with chief place of business at Toronto.

INDUSTRIAL PROGRESS

MACHINERY AND MANUFACTURING NEWS would be pleased to receive from any authoritative source industrial news of any sort, the formation or incorporation of companies, establishment or enlargement of mills, factories or foundries, railway or mining news, etc. All such correspondence will be treated as confidential when desired.

J. M. Poirier will start a carding mill at Waterloo.

The Western Bay Company will erect a factory at Calgary.

Fort William will erect an electric light sub-station to cost $10,000.

The Ideal Bedding Co. will increase their factory capacity in Winnipeg.

W. D. Douglass, of Winnipeg will build a sheet iron working factory.

James Murchie Sons Co. will erect a saw mill near Gleason's Cove, N.B.

The McGill Chair Co., of Cornwall, will build a new factory 150x60 feet.

J. Burnside, of Hamilton, will start a sash and door factory at Lethbridge.

J. M. Diver will shortly commence work on a match factory in Sarnia.

The capacity of the McDonald box factory at Peterboro will be increased.

A local syndicate of Eburne, B.C., will erect a glass works at that place.

The Crown Broom Works of Vancouver will build a new factory in that city.

The city of Toronto will purchase an asphalt plant that will cost about $20,000.

The Miramichi Lumber Co. will build mills at Chatham, at a cost of about $50,000.

Toronto will call for tenders for a new pumping station to cost about $12,000.

The Montreal Terminal Cartage Company will build a warehouse to cost $137,000.

The York Radial Railway Co. have commenced work on a new power house at Keswick.

The Cockshutt Plow Co., of Brantford, will make extensive additions to their plant.

The Sabey Lumber Co., Ballard, Wash., will build saw mills an Burrard Inlet, B.C.

The Chatham Fruit Growers' Association will erect a factory and warehouse at that place.

The Grand Trunk will erect a $1,000,000 hotel at Ottawa. Plans are already drawn up.

C. S. Battle, and others, of Vancouver, will erect a big lumber mill on Burrard Inlet, B.C.

A new steel bridge 160 feet long will be built at Doaktown, N.B., by the Intercolonial Railway Co.

Contract has been let for the structural steel to be used in the new steel plant at Welland, Ont.

The Great West Saddlery Company, Winnipeg, will build a factory and warehouse at Saskatoon.

Sault Ste. Marie will submit a by-law to guarantee bonds of a plough company to the extent of $15,000.

The Hudson's Bay Company, of Winnipeg, ask for tenders for a brick boilerhouse and chimney.

The National Trust Co., Toronto, offer for sale the factories and lands lately held by the York Loan Co.

Peter Weiler, of Wetaskiwin, Alberta, is making arrangements to build and run a brewery at that place.

James Sanders will erect a grist mill at Esterhazy, Sask., the town having granted him a bonus of $3,000.

The Sharples Separator Company will erect a factory in Toronto for the manufacture of cream separators.

Wolseley, Sask., will submit a bylaw to raise $20,000 to erect a fire and town hall, and buy fire-fighting apparatus.

The city of Vancouver will buy a large rock quarry to supply municipal works, and will operate it by water power.

The Dexter Mill Co., of Marysville, Washington, are contemplating establishing a shingle mill in Vancouver.

Winnipeg has placed an order for 25,000 barrels of cement with the International Portland Cement Co., of Hull, Que.

A Michigan syndicate has purchased 17 acres of timber land from W. H. Higgins, Eburne, B.C., for a saw mill site.

The Stanley Smelting Works of Bannockburn shipped a carload of pure lead to Toronto recently, which brought $98 per ton.

Joseph Battle, of Thorold, has been awarded the contract for grading for the electric road from St. Catharines to Welland.

The Sawyer-Massey Co. will erect a large warehouse in Hamilton, and the Norton Mfg. Co. will increase their buildings.

The Coast Quarries Co., operating at Burrard Inlet, B.C., is making application to use the Granite Falls for power purposes.

The graphite discovered by Neil L. Campbell, at French Vale, Cape Breton, has been shown to contain 70 per cent. of graphite.

It is reported that the Canadian Locomotive Construction Co. will establish a plant employing 1,500 men at Halifax.

Ross-Harris Company, Montreal, have secured a contract to build 50 miles of C.P.R. road from Parry Sound to Byng Inlet.

J. H. Fryer and others, of Galt, will go into the manufacture of malleable iron castings. They will be capitalized at $100,000.

The Tait-Carss Lumber Co., of Huntsville, Ont., will erect a new dry kiln, and have a railway siding run to their works.

Campbellford, Ont., will submit a by-law to raise $75,000 to erect a new dam and power house, to develop 9,000 horse-power.

The Robertson Machinery Co., of Welland, are about to erect a large new building to accommodate their increasing business.

A large flow of natural gas has been struck south of Hamilton, on the route of the Hamilton, Caledonia & Lake Erie Railway.

The mica mines in Hastings county are being successfully operated, and a large quantity of mica is being marketed from them.

Four new elevators will be built in Weyburn this year by the Dominion, Northern, McKinnon and Weyburn Lumber Companies.

The Ottawa Dairy Co. are installing a plant for the manufacture of skim milk into powder, which is used for many purposes.

A proposal to establish a glass factory at Eburne, a suburb of Vancouver, on the North Arm of the Fraser River, is taking shape.

Waterloo will vote on a by-law to lend $7,500 to the Specialty Knitting Co., of Galt, in order to establish a factory in the former town.

A heavy output of ore is maintained over the whole Kootenay district. The total shipments for the last 12 months were 338,228 tons.

Stephens, Hepner & Co., of Port Elgin, are negotiating with Peterboro' with a view to establishing there. They employ 60 hands.

The Transcontinental Railway Commission will shortly call for tenders for 50,000 tons of 80-lb. rails, and 2,500 tons of angle irons.

The Hamilton Power Company will spend a quarter of a million dollars in increasing its plants at Northfield and Departure Bay, B.C.

Ten thousand men will be needed by J. D. McArthur, of Winnipeg, to carry on the Winnipeg-Superior section of the Grand Trunk Pacific.

William Mackenzie has purchased for $5,000,000 the Conrad mines in British Columbia. These mines were bought last year for $160,000.

The Terminal Warehouse & Cartage Co., Montreal, will erect a building to cost $137,000. The building will be of solid brick, 192 x 99 feet.

A. E. Williams and Crown Attorney

Hart, of Vancouver, are at the head of a company who will build and operate a million dollar pulp mill.

The Belleville Rolling Mills have been sold to J. Wardrope, of Ottawa, who has been acting for a syndicate. New machinery will be installed.

The Dominion Government will erect a ten-story building on Front street, Toronto, next to the Customs House, to be used as a receiving warehouse.

The annual report of the U. S. Steel Corporation, for 1905, just published, shows a gross earning of $585,000,000, and a net earning of $120,000,000.

The oil refinery of the Imperial Oil Company, which was recently destroyed at Sarnia, will be rebuilt at once with increased manufacturing facilities.

The Canadian White Co. are engaged upon an immense work in Montreal in the excavation of ground for a new cold storage property in that city.

Seaman, Kent & Co., Toronto, will establish a factory at Port Arthur to employ from 30 to 50 hands for the manufacture of hardwood flooring.

The Charlottetown Foundry & Machine Co., of Charlottetown, P.E.I., have opened up their new foundry, and make a specialty of heating plants.

Meaford citizens voted a loan to the Georgian Bay Milling and Power Company in order to develop electrical power for lighting and industrial purposes.

The Hillcrest Railway Coal & Coke Co. will apply for a charter to build a railway from Morrissey, B.C., through the Crow's Nest Pass to Cardston, Alta.

The Amherst Foundry Co., Amherst, N.S., have placed an order for a 2½-ton single-beam traveling crane with the Smart-Turner Machine Co., Hamilton, Ont.

The establishing of a fibre factory is contemplated in New Westminster, B.C. The promoters of the concern are the John Doull Miller Company of New York.

The Peterborough Light & Power Co. has offered to furnish Peterborough factories with power up to 2,000 horsepower at the rate of $20.00 per horsepower per year.

The Port Arthur Lime, Sand, Brick Co. are having a plant shipped from John Inglis & Sons, and it is expected that operations will be commenced on June 15.

Stevens, Hepner & Co., brush and broom manufacturers, of Port Elgin, have asked the town to install a waterworks system, otherwise they will go elsewhere.

The Burrill Foundry Company has secured a site in Brantford, and will build a factory thereon. It is expected that everything will be running by the 1st of June.

The Hedley Shaw Milling Company of Thorold, Ont., may locate at Port Colborne if certain trackage and switching privileges are not allowed them by the former town.

The Knechtel people, of Walkerton, will enlarge the Sieling furniture factory to accommodate 25 more hands. The addition will be 50 x 75 feet, three stories high.

The British Columbia Pine Timber Co., of Vancouver, will build a saw mill at Kaien Island, and have a contract to supply 500,000 ties for the Grand Trunk Pacific.

The United States Government will shortly commence the widening of the Soo Canal, which will be the first step in improvements that will amount to over $6,000,000.

Final arrangements have been made for building the Hamilton, Galt and Guelph electric railway. A bridge on the high level across Desjardins Canal will be constructed.

Among recent sales of economizers made by the B. F. Sturtevant Co., Boston, Mass., was an installation of plant of the Hamilton Powder Co., Beloeil Station, P.Q.

O. Dunn, of Peterborough, and Edward Young, of Young's Point, will rebuild and operate the sawmill burnt at the latter point last July. The new mill will be 60 x 22 feet.

Assessment Commissioner Forman, of Toronto, is negotiating with a large American steel company, and a brick manufacturing company, to establish works at Ashbridge's Bay.

It is estimated that the consumption of Portland cement in 1905 was approximately 1,346,548 barrels of home product and 718,275 barrels of imported, or a total of 2,004,823 barrels.

The Keewatin Power Company will offer for sale by auction its developed water power on Winnipeg River, near Kenora, Ont. Sale will take place at Russell House, Ottawa, July 5, 1906.

The Dominion Smelter at Boundary Falls, B.C., will be enlarged by the addition of a new furnace and an expenditure of $20,000 on machinery, which will increase the output to 1,200 tons per day.

The Arizona Camp Bay Co. will install a 125 ton capacity pulverizor in their mills at Kenora. It is claimed that a saving of 50 per cent. will be effected with half the former power used.

The only industrial strike (aside from the telephone operators) which threatened Vancouver this season, that of the carpenters has been averted by a mutual agreement between masters and men.

The city of Calgary has ordered a 400 horse-power cross compound Corliss engine from the Robb Engineering Co. This is a duplicate of an engine installed by that city a few months ago.

The Baker Lumber Company will build a saw mill on the Kootenay river near the mouth of the Elk river in British Columbia. C. D. McNab will be manager, with headquarters at Cranbrook.

The Ingersoll Board of Trade is advertising the industrial possibilities of their town in trade papers, and report many replies, which shows that this method of advertising reaches the persons desired.

Recent explorations in Cape Breton have brought out the reports that some of the richest copper properties in the world have been found there. The Department of Mines has taken up the work of surveying.

Drummond, McCall & Co., sales agents for the Algoma Steel Co., have closed a deal for 50,000 tons of 80-lb. steel rails with the C.P.R. These rails are to be used between Port Arthur and Superior Junction.

Wm. Beech has returned to Winnipeg, after spending several months of exploration up near the Hudson Bay. He reports sections of that country to be rich in iron, mica and plumbago, as well as the precious metals.

Chas. Harrigan, acting for a Spokane syndicate, has taken an eighteen months' bond on the Humming Bird gold-copper property in British Columbia. A force of men will be put on at once to develop this property.

The Grand Trunk has asked the Government to permit 50,000 tons of steel rails to enter Canada free of duty. It is said that the rail mills of Canada have all they can do for twelve months, and are unable to fill this order.

Probably one of the least talked of and yet withal the richest copper properties in Ontario is that of the Massey Mining Company, situated about four miles from Massey, Ont., and about the same distance from the Spanish River.

C. M. Hays, Sir Thomas Shaughnessy, E. H. Fitzhugh, F. H. McGuigan, D. McNicoll, and G. W. Leonard, will seek incorporation as the Toronto Union Station Company, with power to erect a union passenger station at Toronto.

The Brockville Mining Co. is developing the mica mine near Elgin, Ont., and has opened works in Brockville for finishing the product. About twelve people are employed, and the outlook is that the industry will become an extensive one.

The Canada Stove Works at Harriston are getting things in shape at their new foundry. The molding shops, machine shops and fitting room contain the latest improvements, and when completed it will be altogether a well equipped plant.

J. M. Moore, of Portland, Ore., is at the head of a body of men who purpose establishing a cyanide system of treating ores, in Victoria, B.C. The advantage of this process is that ores are treated at the mines instead of being sent to smelters.

J. A. Young, of Sydney, C.B., states that a barbed wire factory will be established at Sydney if the Dominion Government will put a tariff on barbed wire. The new enterprise would be financed by English capital and employ a large number of men.

The Canadian Buffalo Forge Co. are furnishing fans, separators, and complete galvanized iron work for exhausting shavings in E. W. Tobin's new plant

at Bromptonville, Que. Similar equipment is also being furnished to Messrs. J. & G. Jardine Co., Rexton, N.B.

The ironfounders of Hamilton have asked the molders to accept 10 per cent. cut in wages. The employers say that the west, which is the principal market, is being taken by American founders, who are near the market. The molders turned down the proposal, and asked for a 10 per cent. increase.

The Chapman Double Ball Bearing Co., of Canada, has shipped a large order of bearings to the Western Canada Flour Mills Co., St. Boniface, Man. This mill is one of the largest and most modern-equipped flour mills in the world, and is using every modern appliance with a view to economy.

Toronto city council has joined in a petition to the Dominion Government to permit municipalities to obtain control of Bell Telephone lines. The petition also memorializes the Government not to increase the capital of the Bell Company unless the company is willing to submit to municipal regulation and provincial control.

A. Jennings & Co., of Montreal, wagon and carriage builders, have just completed what is considered one of the best equipped shops of its kind in that vicinity. Amongst other apparatus is a 25 h.p. Alexander suction gas plant, supplied by Williams & Dadson, of Montreal, with which they purpose making their own light.

Centrifugal pumps have been installed by the Smart-Turner Machine Co., Limited, in the Canada Coating Mills, Georgetown; the John Whitefield Co., Toronto, and the Magnetewan Tanning & Electric Co., and standard duplex pumps have been ordered by E. Long Mfg. Co., of Orillia; Kerr & Foss, Sherbrooke, Que.; Geo. Roberts & Sons, and H. C. Minette, of Gravenhurst.

Among the boiler contracts at present being filled by the Jenckes Machine Co., of Sherbrooke, Que., is one for a new boiler plant which the A. Gravel Lumber Co., of Etchemin Bridge, Que., is installing. This plant will consist of four 125 h.p. 72-in. diameter by 16 ft. long high pressure tubular boilers, complete with all fixtures and fittings. Smoke breeching and 600 h.p. feet water heater.

S. J. Ritchie, an Ohio capitalist, has made the statement that immense quantities of red, grey and blue granite are to be found near Bancroft, Ont. The deposits were brought to the attention of Thos. Morrison, of Aberdeen, Scotland, who has had a large experience with granite and marble, and he has declared the granite equal to the best imported to this country.

Wm. McNally, head of the big contracting firm of Montreal, has just returned from the Old Country. Foreseeing the shortage in supplies of cement from the United States, and the incident advance of prices, Mr. McNally made arrangements with some of the Old Country manufacturers for supplies, and has chartered several steamers for the transport of cement supplies, which will deliver abundant cargo at Montreal shortly.

A car barn and shops for the B. C. Electric Railway are to be built in Vancouver on a new site in Mount Pleasant, recently purchased. It is the intention at these shops to manufacture not only parts of cars, and repairs, etc., but also to turn out everything possible to make and in common use in the electric business. The company has at present a car shop at New Westminster, where all the cars for their lines are turned out.

The Alberta Railway & Irrigation Co., Lethbridge, has ordered two 175 h.p. Robb-Mumford boilers from the Robb Engineering Co., making the ninth of these they have installed and running. Two of 200 h.p. are being installed in the new I.C.R. roundhouse at Truro, and one of the same capacity in the power plant of the town of Strathcona, Alta., as well as two of 150 h.p. for the station of the Marconi Wireless Telegraph Co., of Glace Bay.

Among recent patents granted in Canada, Fetherstonhaugh & Co., patent solicitors, Montreal and Toronto, are: R. Thompson, governing mechanism for elastic fluid turbines; M. M. Pearson, elastic fluid turbines; J. P. Sinclair, hot water heating system; C. W. Gay, paper box machines; E. A. Mason, wheel guards for railway cars; J. C. Harmer, device for removing frost and steam from windows; J. W. Stanley, vehicle axles; H. E. Moffatt, oil extractors.

J. R. Booth, Ottawa, has placed an order with the Jenckes Machine Co., of Sherbrooke, Quebec, for a water wheel plant to run his new paper mill. The plant will consist of a pair of 48-in. special graduating gate type Crocker turbines, to develop 875 h.p. under 20 feet head, running at 155 r.p.m. The turbines will be mounted on a cast iron draft chest, set in concrete flume. The same company is also building two Port Henry pulp grinders, in addition to seven already furnished Mr. Booth.

A variety of patents have been issued by Marion & Marion, patent attorneys, Montreal, in Canada recently, included among which are: hand-operated spraying device, Hans Mikerov, Berlin; electric incandescent lamp, Otto Feuerlin, Charlottenburg, Germany; explosives, Gustav Reschke, Hamburg, Germany; air and gas mixer, G. Graap, Berlin, Germany; rail cleaner, H. Quiertier, Dunedin, New Zealand; hydraulic clutch, George Sparks, Fairview, England; lead and silver recovering process, J. Asbeck, Germany.

The Canadian Chrome Co., of Thetford Mines, are installing an additional 10 stamps in their stamp mill, which will give it 20-stamp capacity. Since commencing operations about a year ago this company have met with excellent success in marketing their product, which is of an especially fine grade of chrome iron concentrates, hence the present increase of plant. The additional equipment was furnished complete by the Jenckes Machine Co., of Sherbrooke, Que., who were also contractors for the first 10 stamps.

The Lake Superior Corporation and the Dominion Iron & Steel Company, have announced that they will both tender for the contract for 50,000 tons of steel rails to be awarded by the National Transcontinental Commission. As the rails are for this year's delivery it was thought that the Canadian companies would not be able to take the order. It is probable that the contract will be divided between the Canadian companies, as with the tariff they can quote a lower figure than the English manufacturers, who are the closest competitors.

The Canadian Buffalo Forge Company, in Montreal, are rushed making air washers, and are at present installing six very large ones for purifying and humidifying air supplied for ventilation. The system consists of a spray through which the air passes and an arrangement of baffle plates, removing the moisture and dirt with it. With this equipment it is claimed that no matter how dusty the source of supply, the air entering the building will be pure, fresh and properly moistened. An attachment is furnished for automatically controlling the temperature in the spray chamber, thus automatically determining the humidity.

Work on the new municipal electric lighting plant for Drummondville is about to commence. The Standard Construction Co., of Montreal, have the contract. The contract for the hydraulic machinery has been sublet to the Jenckes Machine Co., of Sherbrooke, Que., and the contract for the generator has been sublet to the Canadian General Electric Co., Toronto. The water wheel plant will be composed of one 55-in. special Crocker turbine, vertically set in steel case and complete with gearing, bridgetrees, shafting, etc. Under 11 feet head the turbine will develop 240 h.p. at 90 r.p.m. The generator will be of 150 k.w. capacity.

The hoisting engine equipment of the Asbestos & Asbestic Co., Asbestos, Que., near Danville, has been increased this Spring by the addition of four 9 x 12 special cableway hoisting engines, as built by the Jenckes Machine Co., of Sherbrooke, Que. This hoisting engine was designed especially for cableway service, having one drum for hoisting purposes and a separate independent drum for operating the carriage on the cable. It has been extensively adopted by the asbestos mines in the Province of Quebec, also to considerable extent by the coal mines in Alberta. The Johnson's Company, of Thetford Mines, have lately installed two of these engines.

The Northern Electric & Mfg. Co. have just about completed one of the largest and best equipped manufacturing plants in Montreal. In their cabinet shop, equipped some months ago, they had installed 79 Chapman double ball bearings, and for the main plants recently completed they have ordered 140 more. Other firms to adopt these bearings in their plants with a view to using the most modern methods available are the Canadian Fairbanks-Morse Mfg. Co., the London Machine Tool Co., Hamilton; the Hamilton Cotton Co.; the Singer Mfg. Co., St. Johns, Que.; the Canadian Copper Co., Copper Cliff, Ont.; and the Oshawa Steam & Gas Fitting Co.

The 250 h.p. electric hoist which was built for the Granby Smelter, at Phoe-

nix, B.C., by the Jenckes Machine Co., of Sherbrooke, Que., has recently been shipped. The fact that this hoist has been built by a Canadian firm is noteworthy, as heretofore electric hoists of large size have been regularly imported from the United States. The hoist has two conical drums, each 8½ feet diameter at large end, 5 feet diameter at small end and 5½ feet long, both drums being capable of independent operation through the medium of powerful friction clutches. The capacity of the hoist is a load of 10,000 lbs. on either drum at 500 feet per minute, and the shipping weight in the vicinity of 50,000 lbs.

Kaien Island, the much-exploited and much-advertised, and supposed terminus of the Grand Trunk Pacific in the east is the site chosen for the location of a mill by the B. C. Pine Timber Co., an organization recently formed here, and which has as a starter an order to cut 500,000 ties for th new transcontinental line. W. D. Hays, a brother of the general manager of the G. T. P., associated with a number of local men, is interested in the mill. The machinery for the mill has been ordered from the east and will be forwarded to Kaien Island as quicly as it arrives, for the contract for ties is for early delivery and it is anticipated that work on cutting them will begin by mid-summer..

Recent installations by the McEachran Heating & Ventilating Co., Galt, Ont., include lumber dry kilns for Sherlock-Manning Organ Co., London, Ont.; Dyment-Baker Co., London, Ont.; New Glasgow Mfg. Co., New Glasgow, N.S.; A. McDonald Co., Peterboro; cloth dryers for Medicine Hat Woolen Mills Co., Medicine Hat, Assa.; brick dryers for Imperial Land Co., Sturgeon Falls, Ont.; blast heating systems for W. A. Greene & Co., Waterloo, Ont.; Belleville Portland Cement Co., Belleville; Imperial Paper Mills Co., Sturgeon Falls, two mills; Dyment-Baker Co., London; planing mill exhaust systems for Ottawa Lumber Co., Ottawa, Ont.; Laverdue & Sons, Ottawa, Ont.; Dyment-Baker Co., London, Ont.; London Box Co., London, Ont.; Cushine Bros., Regina, N.W.T.

After a short cessation of operations the Laurie Engine & Machine Co., Limited, of Montreal, known from Sydney to Vancouver as manufacturers of the Laurie Corliss engine, has renewed operations with increased energy. The officials of the company are: President, Wm. Yuile, vice-president, David Yuile; managing director, Herbert Yuile; secretary-treasurer, A. D. Madley; directors, C. E. L. Porteous, C. W. Davis, William Davis, H. Yuile and Alex. Ross, superintendent. With the addition of new energy and fresh capital, and the thorough requipment of the firm in all its departments, the Laurie Engine & Machine Co. are prepared to go ahead on a larger scale than in the past and manufacture, besides the former lines, big castings for structural work and all kinds of contractors' supplies. Some of the corporations in Canada that have installed Laurie engines include the Montreal Street Railway Co., the Winnipeg Electric Street Railway Co., Toronto Railway Co., the Dominion Iron & Steel Co., the Canadian Rubber Co., Gazette Printing Co., Merchants' Cotton Co., Windsor Hotel, Montreal; Ogilvie Flour Mills Co., Canadian Pacific Railway Co., British Columbia Electric Railway Co., Linde British Refrigeration Co., Montreal Light, Heat & Power Co., and many others equally important.

Enterprise Foundry Enlargements.

The Enterprise Foundry at Sackville, N.B., in which Messrs. Emerson & Fisher, of St. John, N.B., are largely interested, is to be further enlarged. A short time ago it became necessary to enlarge the foundry and now increasing business has made an addition to the warehouse and the erection of a new office building necessary. It is expected that the new buildings will be ready for occupancy in July. The addition to the present warehouse will give the foundry a three-storey warehouse 160 x 40 feet. The new office building will be a two-storey structure 40 x 35 feet, fitted with a vault and all the latest conveniences.

New Construction Company.

A new construction company has been formed at Montreal, under the name of the Smith Marble & Construction Co., with a capital of $40,000. The company obtained a Federal charter and it has been decided to erect a large factory, ground for this purpose having been secured at Cote St. Louis. The new building will be two storeys high and of large proportions, the approximate cost being fixed at $10,000. They will contract for interior marble, concrete and cement flooring, tiling and general construction work, giving employment to a large staff of workmen. The officers of the company include D A Campbell, president; W. J. Henderson, secretary; A. L. Smith, treasurer; Peter Smith, managing director.

Foundry Convention.

The tenth annual convention of the American Foundrymen's Association is to be held in Cleveland, Ohio, June 5, 6 and 7. For this convention an attractive programme has been arranged, and everything points to a most successful convention. The annual gathering of the Associated Foundry Foremen will take place in Cleveland on the same days, beginning with June 4. Joint sessions will be held during the week, and both associations will take part in the various excursions arranged.

Change in Tool Business.

The Cincinnati Lathe & Tool Co. have recently purchased the lathe business of the Fosdick Machine Tool Co., of that city. The plant is situated in the heart of the machine tool district and is in full running order. The president of the company, Mr. W. C. Heindel, was connected with the Cincinnati Milling Machine Co. for the past ten years, and the superintendent, Mr. A. B. Sowden, has been building lathes for the past twenty years.

New Blast Furnace.

The capitalists behind the Canadian General Electric Co. and Canada Foundry Co. propose to organize a million dollar company to erect blast furnaces on the Niagara Peninsula to work in connection with the shipbuilding yards at Bridgeburg and supply material to the Canada Foundry and other enterprises closely allied to the parent concern. The difficulty in securing pig iron, now that the manufacture of steel rails has been taken up in Canada, and the prevailing high prices have, it is understood, much to do with the proposed enterprise. The projected furnaces will probably have an output of 200 tons a day at first, and of this, the Canada Foundry Co. would need one-half. The new company will likely be formed at once, and as the Niagara Peninsula is to be the location, the electric process of smelting may be used. The shipbuilding yards at Bridgeburg are being rushed to completion, in order that the owners, the Canadian Shipbuilding Co., may get to work immediately on the construction of the largest steamers ever built in Canada. One is a 10,000-ton steel freight steamer for the Chicago and St. Lawrence Transportation Co., and the other is a new palace steamer for the Canadian Pacific Railway for use on the upper lakes, possibly the new Victoria Harbor route.

Automobile Exhibition.

The Automobile and Motor Show held in the Granite Rink, Toronto, was such a pronounced success that it has been decided to make it an annual affair, and also national in character. Two rinks were utilized for the purpose, both being handsomely and artistically draped with bunting, while during both the afternoon and evening music was furnished by an orchestra in each of the galleries. In one department was included the launches and automobile accessories, gasoline engines and supplies of all kinds, while in the other building the automobile show proper was carried on. Excellent exhibits were shown by a large number of firms, noticeable among which were the Canadian General Electric Co.'s electrical display, the Toronto gas and gasoline engine exhibit, the demonstration of the Chapman double ball bearing, Queen City Oil Co., the Defiance Iron Works of Chatham, Walter Nicholls Motor Boat Co., and many others.

Beautiful Calendars.

The monthly calendars being issued by the Allis-Chalmers-Bullock, Limited, are attracting considerable attention and coming in for a good deal of favorable notice. Those who have been fortunate enough to secure a set to date will no doubt appreciate them and keep each number, containing, as it does, the crest of one of the provinces of the Dominion of Canada in a gold and colored design. The April calendar has on it the crest of Nova Scotia. A card to the publicity department of this firm at Montreal will bring copies of this calendar to any reader of Canadian Machinery.

The Pembroke Electric Co. have recently awarded contracts for the machinery for their new power plant on the Black River, a few miles from Pembroke. The hydraulic plant consists of two 900 horse-power units, each composed of one special 30 in. cylinder, Gate-Crocker turbine, operating under 120 feet head. Each wheel will be enclosed in a steel case 7 feet in diameter, made of ½ in. plate, fitted with heavy cast iron discharge elbow, both units substantially mounted on steel girders, and complete with draft tubes, etc., and two Lombard Type "B" water wheel governors. The water will enter both cases from underneath, a gate valve being placed in each inlet pipe. The water wheel runners will be made of bronze, and each wheel will be direct connected to a 500 k.w. alternating current 3-phase Westinghouse revolving field generator. For driving the exciters there will be provided two 15 in. turbines, each enclosed in steel case and each developing about 50 horse-power. These wheels are also built with bronze runners. Under 120 feet head they run 900 r.p.m., and will be direct connected to the exciters. The hydraulic machinery is being furnished complete by the Jenekes Machine Co., of Sherbrooke, Que., and the order for the generators and exciters has been placed with the Canadian Westinghouse Co., Montreal.

To Electrify the C. P. R.

As soon as the officials of the Canadian Pacific Railroad are satisfied with the results of the experiments being carried on by the New York Central and other American railways in connection with their electrification over certain districts, it is intended to proceed at once with adopting the electric system over the trunk lines on parts of the route where water power is available. While other railways have been expending enormous sums experimenting, they have proven beyond contradiction the utility of the electric locomotive and its obvious advantage over the steam engine for fast runs and frequent service. Both direct and alternating current systems have been adopted, and when the company is able to decide between these work will be proceeded with. It is intended to electrify the line between Montreal and Quebec in the first instance, and later to carry the principle to other lines.

An Ambitious Town.

A quiet development is going on all over the Province of Ontario, manufacturers without exception being almost taxed to capacity to keep abreast of orders, and accordingly expansion is the serious problem confronting them all. Of all the towns and cities which are feeling the impulse of new life, perhaps Galt stands in the very forefront. One has but to visit that busy, hustling, conservative but progressive town to be impressed by the boom that appears to have struck the place, and not only it but the chain of Waterloo county municipalities connected by electric railway —Galt, Preston, Berlin and Waterloo. Galt has several new industries starting this Summer, the most important of which is a malleable iron foundry, now being erected, and to begin operations about the first of June with about eighty hands. At the head of it as managing director is Mr. J. H. Fryer, for years of the firm of Thomas Todd & Son, export hay and grain dealers, and this year's president of the Galt Board of Trade, as well as an alderman, while in the company are some of the wealthiest men in the town and district. Another interesting industry the town has secured, which will make a departure from the iron industries for which the place is noted, is a whitewear factory, which will be in operation within a month. (50 hands). Several smaller industries are being organized, and the influx of labor to all these will mean the erection of several score of houses. At the present time there is not an empty house in the place, even single rooms being rented above stores and offices, and rents are advancing steadily, these features being, of course, characteristic of all growing places. It is probable that steps will be taken within a few days by the board of trade to have workmen's houses erected in large numbers. Last Summer P. W. Gardiner & Son began the erection of a modern planing mill, and it is now just completed, which will facilitate the putting up of houses at the lowest possible cost.

Recognizing the importance of Galt as a manufacturing point, the Canadian Pacific Railway last year converted it into a divisional point, expending over $40,000 on the improvement of its property there, and having acquired a controlling interest in the Galt, Preston & Hespeler Electric Railway, and the Preston & Berlin Electric Railway, which has freight privileges, it has given that road access to "Busy Berlin" as well. Galt is connected by electric railway with Brantford and Paris, to the south, and another road is being mooted to Hamilton and Guelph. A by-law granting street railway switches to manufacturers was passed by three to one on the 5th of April, and this is but an indication of the liberal policy which the people entertain toward manufacturers, and which is quite a change from the spirit of a few years ago. The board of trade, which is one of the most active boards in the country, is largely responsible for the new sentiment, and friends of the good Scotch town will be glad to know that it is making progress so substantially all along the line.

Vancouver City Council is to spend $6,000 in buying water meters to place on the pipe lines of all users except residences. It is found that some disproportionate rates are paid, and to make it nearer the fair thing for all for other than domestic purposes, meters are to be put on. Hitherto practically the only concerns having meters on their mains were the mills and other large manufactories, especially where steam power was generated.

HAVE YOU TRIED OUR WANT COLUMNS?

RATES

One insertion—25c. for 20 words; 1c. a word for each additional word.

Yearly rate - $2.50 for twenty words or less, 10c. a word for each additional word.

The above does not apply to notices under the head of "Machinery Wanted." These notices are inserted free for subscribers.

MACHINERY FOR SALE.

FOR $650—Half value—one 10 h.p. engine; one 40 h. p. boiler, 50 ft. stack; 1¾ acres land; good house, mill building and stable; suitable for small factory; or will sell machinery separate; location, Hepworth, Bruce County. Write R. Murdoch, Sault Ste. Marie, Ont,

SITUATIONS VACANT.

WANTED—For a well-established concern abroad, a live advertising man, well educated, accustomed to printers' work and to high-class advertising through all channels; knowledge of European, and especially of English, methods and ideas an advantage. State age, experience (fully), remuneration sought, and when disengaged to Advertiser, CANADIAN MACHINERY, Montreal.

REQUIRED for a "small arms" factory abroad an educated engineer with experience of very high-class interchangeable work produced by the latest automatic and repetition methods; must be active, energetic, thoroughly at home in jig and fixing work and up-to-date generally. Write fully as regards experience and salary expected, also stating age, etc., to Box W, CANADIAN MACHINEY, Montreal.

EDUCATIONAL

MECHANICAL drafting pays; complete course, $5. Browning Press, Collinwood, O.

BUSINESS CHANCES

MACHINE SHOP — Established 12 years; lathes, drills, grinders, etc.; patterns for 3, 6, 15 and 25 h p. gasoline engines; automobile engine patterns for 6, 12 and 16 h.p.; also several other patterns and engines in stock at present; repair trade paying big profits; in Canadian town of 45,000 inhabitants; must be sold at once on account of ill-health of proprietor; price about $3,000. Box 301, CANADIAN MACHINERY, Toronto.

LOCATION WANTED—We are seeking a location for a steel stamping industry that will give employment to about 75 hands; owing to large demand for articles of this kind in Canada, we are desirous of locating there; what inducements can a progressive city offer? Address reply to The Crescent Machinery Co., 1,535 Williamson building Cleveland, Ohio.

INDUCEMENTS SOUGHT—A firm employing over a hundred hands, would like to get full particulars of inducements offered by Canadian towns and cities to branch of reliable and well established concern. Reply to Manufacturer, c/o CANADIAN MACHINERY, Toronto.

Feature—Improved Arm

Have you seen the

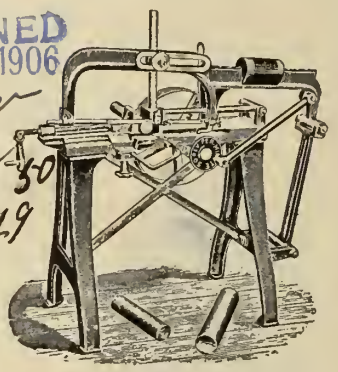
IMPROVED POWER HACK SAW

working? Make it your business to do so.

It cuts Bars 6 x 6, either round or square, and after work is placed in vise the saw requires no attention. It stops automatically when piece is cut off.

The **Improved Arm** keeps saw perfectly in line at all times.

One saw with each machine. 12 and 14 in. saws in stock. Write for prices.



TAYLOR & McKENZIE, GUELPH, ONT.

GENERAL MACHINERY

HAVING ANY TROUBLE WITH THOSE

HACK SAWS?

If you want to cut Iron, Steel, Brass or any other Metal—**and cut it fast**—there's nothing equal to a **UNIVERSAL Hack Saw.**

UNIVERSAL Hack Saws are used all over the world—wherever it's necessary to get the cutting done quickly.

And **UNIVERSAL Hack Saws** outlast any other Hack Saws made. **Test them and see!**

Expert Cracksmen have failed to break H. Steel Castings.

Scientists and Machinists have branded H. Steel as perfect steel.

Made in any size and to suit any purpose. Absolutely free from blow holes.

Will last longer than any other casting. Sound to the core.

We make **MILL MACHINERY, CASTINGS** and **MACHINERY** of all descriptions.

A specialty is made of H. Steel, because the patent is ours and it can be had only from the

OTTAWA STEEL CASTING CO.
OTTAWA, ONT. LIMITED

DO YOU EVER GET OUT OF TEMPER WITH SOME TOOL STEEL?

After the crucial test the edge is done up. When high speed is attained the cuts are not so deep—this is the story of ordinary tool steel, perhaps the kind that you are using.

Decide to be progressive—to minimize losses, expedite work, ensure satisfaction. Decide to get all the profit that rightfully is yours.

ALPHA
HIGH-SPEED STEEL

is the steel to get. It is the best-working tool steel on the market. No machine shop can do fine work without "Alpha." It has a record for sterling service.

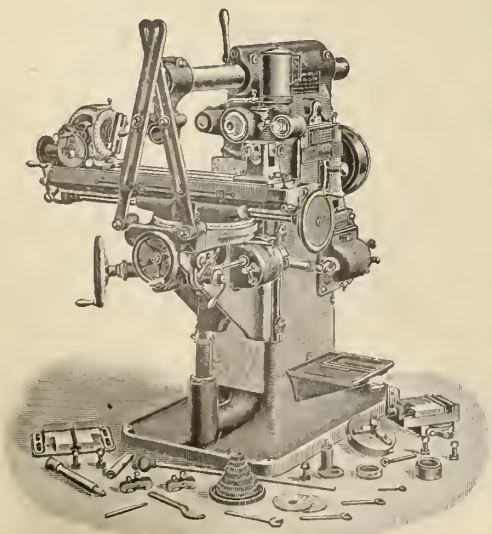
BROWN & SHARPE MANUFACTURING CO., Providence, R.I., U.S.A.

Simplicity and Efficiency

Features of the Feed Box on a

B. & S. UNIVERSAL MILLING MACHINE



The Drive is direct from spindle to gear case by chain and sprocket wheel.

The Mechanism is simple and easily controlled by the movement of index slide and levers.

The Gearing is all spur gears, hardened, running on steel shafts with bronze bushings.

In the operation of this feed box there is practically no loss of power by friction and the efficieny at all times is unusally great. Its power is limited only by the capacity of the machine.

Pamphlet, describing the machines in detail, sent upon application.

Experience Tells

That is the reason of our confidence that your satisfaction is assured after trying our

IRON AND STEEL FORGINGS

All our work is proved by over

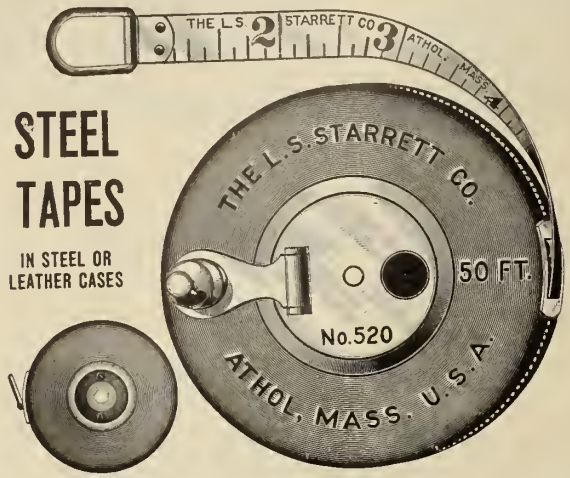
STARRETT TOOLS

ARE THE STANDARD

FOR ACCURACY, WORKMANSHIP, DESIGN AND FINISH



STEEL TAPES

IN STEEL OR LEATHER CASES

In our tapes the figures denoting feet are smaller than those denoting inches. Two reasons for this :

This dissimilarity of figures materially lessens (in fact ought to entirely prohibit) the liability to erroneous readings that frequently occur through the uniformity of all figures in steel tapes of other makers.

The smaller figures, denoting feet, allow the graduation line under each to be plainly visible, instead of being obliterated by the usual larger figure.

Graduated in feet, inches and eighths of an inch, or in feet, tenths and hundredths of a foot.

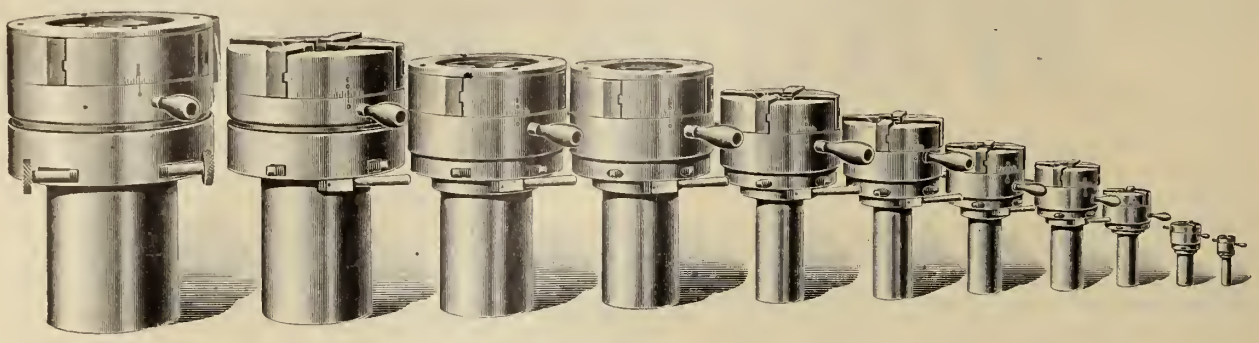
TOOLS FOR EVERY REQUIREMENT



Our style "**D**" **SELF-OPENING** and **ADJUSTABLE SCREW CUTTING DIE HEAD** cuts right or left hand threads of any length—standard or special pitch.

Quick and accurate varations may be made in the diameter of threads for a tight or loose fitting screw, as desired ; and as the dies are adjusted simultaneously, the greatest accuracy is assured.

The **DIES** are opened automatically by stopping the travel of the turret slide.

This tool saves a lot of time and money when used on screw machines, turret lathes or the carriage of engine lathes.

If you want to reduce cost and increase output, send samples or blue print of your work, and we will quote price on the proper size **DIE HEAD** or cover your requirements.

Motor Drive

Merrell Motor and Engine Driven Machines

We can furnish these machines with motors for any direct current. The vise is self-centring and is actuated by a rack and pinion to feed the pipe into the chasers. The head of these machines can readily be removed from the base and used as portable hand machines. The chasers can be sharpened by grinding and can readily be replaced by chasers cutting any style or pitch of thread, either right or left. The machines are made in four sizes—Nos. 5½, 6½, 9½, 11½.

New Graphite Lubricant

Have you read the STORY of Canada's New Lubricating Graphite? This wonderful discovery is a money saver.— It prevents hot boxes and pins, groaning cylinders, etc.— It reduces oil and grease consumption by one-fourth.— It increases the compression of Gas and Gasoline Engines. —It remains suspended in oil and will feed through any lubricator.—A little does the work. This knowledge means money in your pocket. **A POST CARD WILL FETCH YOU THE STORY AND A SAMPLE PACKAGE. WRITE TO-DAY.**

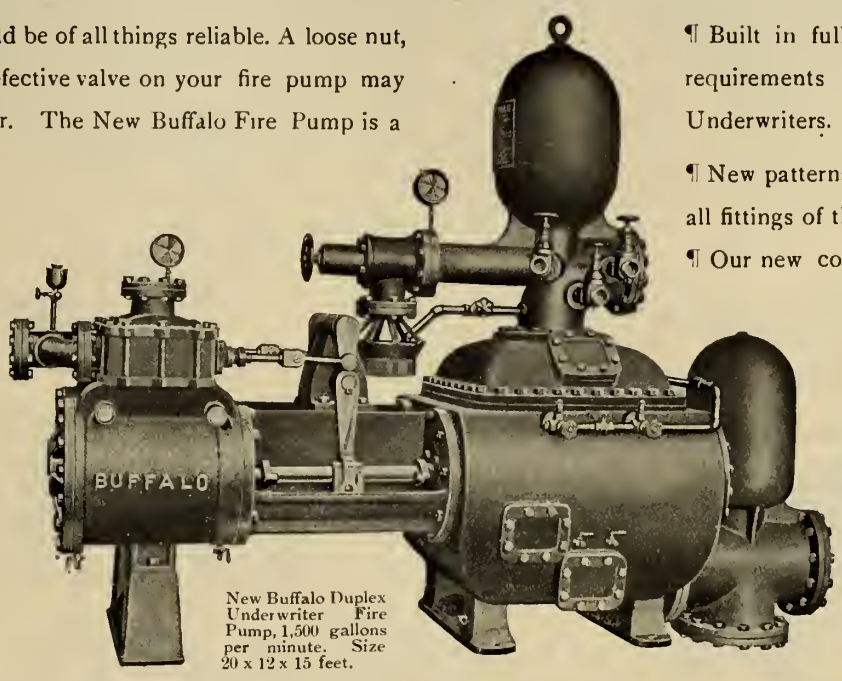
FIRE PROTECTION—BUFFALO UNDERWRITER PUMP

¶ Fire protection should be of all things reliable. A loose nut, sticking piston or a defective valve on your fire pump may some day spell disaster. The New Buffalo Fire Pump is a study in reliability. Its use is a guarantee of effectiveness at any and all times.



New Buffalo Duplex Underwriter Fire Pump, 1,500 gallons per minute. Size 20 x 12 x 15 feet.

¶ Built in full conformity with the requirements of the Factory Fire Underwriters.

¶ New patterns used throughout and all fittings of the highest class.

¶ Our new complete catalogue will soon be ready for distribution. Let us add your name to the list.

Buffalo pumps, both reciprocating and centrifugal, are built in a complete line of sizes, from boiler feed to waterworks service. They are newly designed and conservatively rated and embody only such features as have been fully approved by years of service.

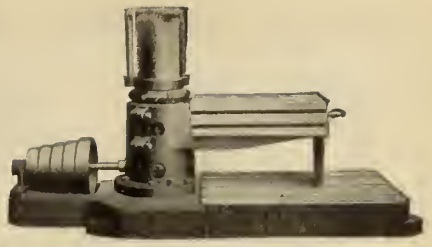
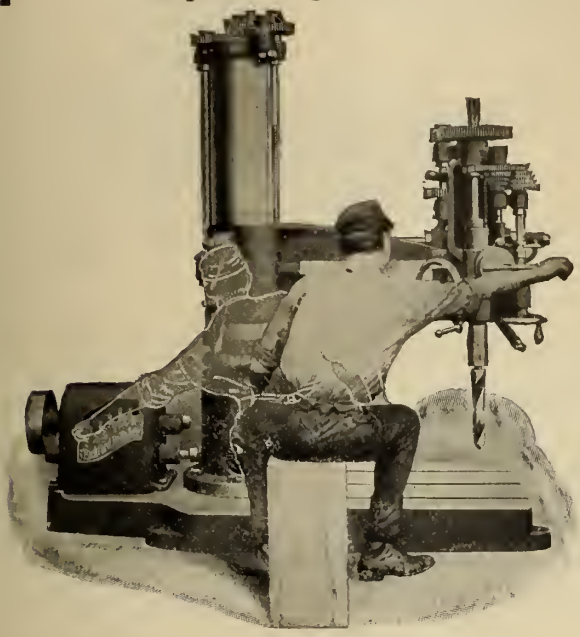
Has Greater Productive Capacity

than any Upright ever built—our 30-in. RADIAL DRILL. Costs but a trifle more and is admirably adapted to light and medium manufacturing, being particularly effective in taking care of the ordinary work as found in the average shop.



Cone Drive and Swinging Table



Bickford 30"-36"-42" Radial Drill

A Few Features

12 speeds when driven through a speed box ; 10 when a cone is used.

Tapping attachment incorporated in the design of the head.

Fitted with any one of six styles of tables.

Circular 1-A for the asking.

CLARK-DEMILL COMPANY, LIMITED, Hespeler, Ontario, Canada

Successors to **CLARK & DEMILL, of Galt, Ontario.**

Western Agents:—THE WATEROUS ENGINE WORKS CO., Limited, Winnipeg, Man.

No. 1-14 Cutter and Reamer Grinder.

WE HAVE A FEW OF THESE MACHINES READY FOR IMMEDIATE DELIVERY

This machine is distinctly a cutter grinder, and was designed to fill the want for a machine to sharpen milling cutters of all kinds and shapes, without special fixtures or special-shape emery wheels, being heavy enough to eliminate all vibration and still be easily operated. It weighs about 1370 lbs. The table, which has a long bearing on the saddle, has a longitudinal feed of 20 in., cross adjustment of 7 in., with a vertical adjustment of 6 in. Cutters 1 in. to 14 in. can be taken between centres. The table can be used at different angles with the spindle in horizontal plane, by swiveling the knee around the column. The machine is compact, durable, adaptable and a necessity for the busy shop.

Modern Canadian Manufacturing Plants.

ARTICLE XVI.—Plant of Polson Iron Works, Limited, Toronto.

LAST year saw Canada take a bound in the direction of industrial progress that caused some of the older inhabitants to wonder what it all meant. The more progressive, however, were fully conscious of the fact that it was undoubtedly an awakening in the minds of our own population and of other nations to the opportunities the country offered. Many firms came from across the border and established plants of their own to catch the growing business. Not a few Canadian firms grasped the situation and increased their capacity for production. To this latter class belong the Polson Iron Works, Limited, of Toronto, who have, during the past year, built an important addition to their already extensive plant, including a modern steel structure for ship building and a complete wood working department and store shed.

In 1886 this firm commenced business under its present management, although previous to that time the business had been carried on under the style of Wm. Polson & Co., at the foot of Jarvis street. When the present company commenced operations the cite chosen was the present location, and since then important additions have been made from time to time. The officers of the company are F. B. Polson, president and general manager; J. B. Miller, vice-president, the latter being also president of the Parry Sound Lumber Co.; A. H. Jeffrey, secretary, and W. B. Tindall, treasurer, while the following are superintendents of the different departments: W. E. Redway, superintendent of shipyards; J. J. Main, boiler shop department, and Alfred Duncan, machine shop, smith and pattern department.

Plant of Polson Iron Works.—West side of Shipbuilding Department.

Plant of Polson Iron Works.—Main Office.

General Scheme.

The property occupied by the firm comprises an entire block between Frederick and Sherbourne streets, south of the Esplanade and extends to the Windmill Line. In all it occupies about five acres, the reclamation of the major portion having been accomplished within the past three years. This gives a splendid water front and ample opportunities for shipbuilding, the water front being supplemented by two slips, one at the foot of each of the streets named. In all the firm has about 1,500 feet of docks and with 14 feet of water.

The present buildings are all new except the machine and boiler shops, which although not of modern structure, are equipped with the latest and best machinery to be had. The new buildings include a handsome office building two storeys in height, containing the general offices, accountant's and manager's offices on the ground floor, and the naval architect's, engineer's and drafting offices above. It is 80 x 32 feet, and, as may be seen from the illustration showing the accountant's office, is fitted up in most modern fashion.

Early last year work was commenced on the new shipbuilding structure, of unique design, as will be seen from the

RETURNED JUN 4 - 1906

drawing showing the general structure and which was soon completed and in full running order.

Plant of Polson Iron Works. General View from Harbor.

Different Departments.

Adjoining the office building is the blacksmith shop, equipped with a dozen forges, steam hammers and all the other tools necessary for a complete forging department. In the same building is situated the brass foundry and, further along, the power plant. The latter is equipped with two 250 H.P. Heine boilers for power and heating and here is also installed a complete air compressor plant for running the different pneumatic tools throughout the works. The other departments, which are situated in separate buildings from the one already mentioned, include the machine shop, boiler making plant, shipbuilding department and the woodworking and pattern making.

Machine Shop.

In the diagram shown, the general layout and position of the machine tools in the machine shop is given. A glance at this will show the grouping and arrangement as well as the different tools employed. These constitute a complement of machinery such as is necessary to meet the demands of a large plant. There are no particular or unusual points in connection with this machine shop apart from the fact that two of the machine tools are all exceptionally large size. One of these is an English planer 30 feet long, 12 feet wide, and 8 feet high, for the purpose of planing large bed plates of the different makes of engines turned out. Another noticeable machine is a boring mill manufactured by John Bertram & Sons, Dundas, which is designed for boring 18 foot diameter and 66 inch face. The machine shop looks after the machining of the engine parts as well as the repair and maintenance of the plant. The different engines manufactured are the Brown automatic stationary engine, the ordinary slide valve, marine engines of any size, compound and triple, as well as yacht engines of high speed.

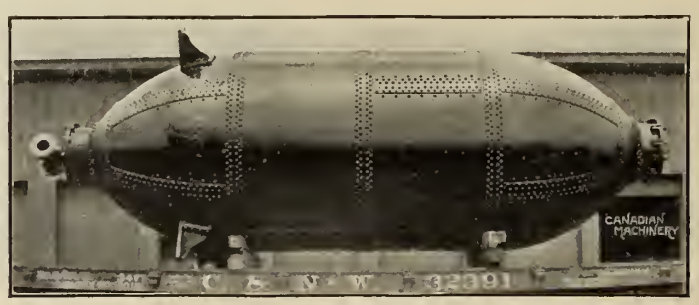
Plant of Polson Iron Works.—View in Shipbuilding Department, showing Heavy Rolls.

Boiler Department.

The boiler department adjoins the machine shop and is connected therewith by a car track which runs through the main departments and joins the main line of railway in front of the premises. This is one of the busiest departments of the entire works and in common with other boiler plants is accompanied by a din and uproar that is almost unbearable to the visitor, but which is looked upon with indifference by the workmen engaged. A large amount of the latest and best boiler making machinery is to be found here, putting the firm in a position to turn out not only a high-class product, but also to manufacture in large quantities. The machines include hydraulic and pneumatic riveters, heavy rolls, punches, steam and hydraulic flanging press and all necessary cranes for handling the material. The output here is quite varied and includes not only the ordinary Scotch boilers of all sizes and up to 200 pounds pressure, but the Heine water tube boiler as well as the Yarrow Mosher & Thornicroft Marshall water tube up to 300 pounds pressure. The illustration shows a large pulp digester made in this plant, its size being shown in relation to an ordinary flat railroad car. Contracts for these are at present on hand for mills in Hawkesbury and Cornwall. During the last year large oil tanks were constructed in this plant for Winnipeg and at present contracts are under execution for some very large steel tanks and malt hoppers for the Canada Malting plant in Winnipeg. Other lines made in this boiler works include air compressor tanks, air locks, and steel tunnels of every description. It is interesting to note in passing that during the past ten years over $600,000 worth of Heine boilers were made in this shop, the latter being but one of the many



Wood Pulp Digester.

lines manufactured, and is under the personal supervision of Mr. J. J. Main.

Ship Building.

This is a branch of manufacture that has not received very much serious attention at the hands of Canadians, but has for some years been carried on to no small extent in the Polson Iron Works, where Mr. W. E. Redway devotes his attention to the peculiar problems confronting the designer of inland boats. The main features in the construction of ships are to be found in the handsome ship building plant already mentioned, which is 300 feet long, 80 feet wide and of two storeys, and an enormous traveling gantry with a span of 75 feet, a lift of five tons and a run of 400 feet.

As the land upon which this new building was erected last Summer had been reclaimed from the bay, it was necessary to take particular precautions in conection with the foundation. This was done by pile-driving the entire ground surface and covering the whole with concrete, thus the property that had before been of little value was now made into a busy manufacturing centre. The building itself, as is shown in the diagram and from the photograph, is of semi-circular construction, even the window frames being of steel. The exterior

apartment fully equipped with all the tools for a planing mill, on the ground floor. The upper storey is fitted up for pattern makers and joiners and contains a full assortment of machinery required for this purpose. Beyond the woodworking shed and towards the water, is situated the pattern storage building, 160 feet long, 60 feet wide and two storeys high, fitted from floor to roof with the accumulation of twenty-five years of patterns, costing hundreds of thousands of dollars.

Plant of Polson Iron Works.—Diagram sh wing Method of Construction.

is of galvanized iron, thus making the structure entirely fire proof, and hence no insurance against fire is necessary.

Adjoining this is the woodworking

The main ship building structure presents a busy appearance. One of the particular features is the abundance of light available for the work in hand, as almost the entire walls and ends are of glass. This last feature is one that is becoming recognized more and more as an absolute necessity for high-class manufacture. On the ground floor are installed hammers, punching shears, counter sinking, drilling, plate edge planing, rolling and plate straightening machinery, some of which are shown in the illustration. These machines are all operated by electricity, except in the case of the steam punches and rivetters. One of the most important apartments is the frame forming which is carried on at the sound end of the building. Here is situated the immense furnace where the frames are heated to their proper heat and immediately in front the metal platform on which they are bent to pattern and conforming to the curve required with the exactness of a small fraction of an inch. Nearby, two boilers supply power to some of the self-acting machines and also heat for the plan-mold loft, the second storey of this building, where all the lines of a ship are laid down full size.

Probably the most notable feature in connection with the ship building yards and without which the economic carrying on of the operations necessary for the erection of the craft would be impossible, is an enormous traveling gantry, size of which has already been given, which has a lift of 50 tons at the centre, travels over 400 feet per minute, traverses its load across a span of 75 feet in one minute, and can raise five ton 50 feet high in the same time. It is operated by three electric motors, one for each motion. It travels on 80 pound rails, and from its different proportions has been built to last. It is said to be the best of its kind in the country and was

made and designed by the engineers of the firm.

Recently this firm has completed a large Government dredge 137 x 44 feet, with 24-inch suction, and another for the city of Toronto, somewhat smaller, having a length of 90 feet with 30 foot beam and 25-inch suction. The large ferry boat, Bluebell, the advent of which Torontonians had looked to with expectation, has recently been launched from these yards. It is 150 feet long, 45 feet beam, entirely of steel. Amongst other boats in course of construction is a stern wheeler, 65 feet by 17 feet, for Lake St. John.

The above description will give the reader some idea of a works, while not on an enormous scale, are still of a size to turn out a large quantity of work, and at the same time, with a growing country, contain possibilities for expansion that are almost without limit.

at 440 volts alternating current being adopted. The power plant to generate the electricity for power purposes is

Double Punch in Operation.

k.w. and 220 k.w. generators, respectively. These engines are of the compound condensing type and will use superheated steam. Besides supplying power, these generators will light the works with about 500 incandescent lights and 125 arc lights. A complete sprinkling equipment with a 50,000 gallon tank on a steel tower is another feature as well as a 1,000 Underwriters' fire pump. The brick stack at the power house will be 110 feet high with a 66-inch inside diameter.

At present the Frost & Wood Co. are calling for tenders for boilers, generators and a large complement of iron and wood working machinery.

Edmonton is having plans prepared for a $115,000 waterworks plant.

Some Engines under Construction.

Heavy Flanging Machine.

FROST & WOOD'S NEW PLANT.

Frost & Wood Co., Smith's Falls, have now well under way a larger plant than ever to replace the one destroyed by fire recently. The new building in course of erection is to be a four-storey brick structure of standard slow burning mill construction, with no openings in the floors, having a floor area of between 140 and 150 thousand square feet. The new buildings are so designed as to give a maximum production, with minimum handling. One feature is that the elevators, stairways, lavatories will all be in fire proof towers outside the building. The roofs are to be of felt and gravel. The best systems of drainage and ventilation are being installed. The heating is to be effected with exhaust steam probably by direct radiation. When completed the firm will employ 500 hands in their new works.

The entire plant will be electrically driven, a system of motor group drives

Hydraulic Rivetter.

isolated from the other building. Two Bellis & Morcom high-speed engines are being installed, direct connected to 140

FINE PUMPING STATION.

Railroads replaced the stage coach, trolley superseded the horse cars—and the new turbine pumps and power are taking the place of the fire engines. This system has been a complete success in Philadelphia, where it was first tested, and the city of Toronto decided to do away with the fire engines in the down-town districts and put in the steam turbines.

The turbine pumps now building have a capacity of 5,000,000 gallons of water every 24 hours, at a maximum pressure of 300 pounds to the square inch. The water will be supplied to a high pressure piping net work, covering the district to be protected.

The pumps are always ready to work—the steam is up—and when fire breaks out, all that is necessary is to couple on the hose to the fire plugs, and the water pours out. This does away with fire engines altogether.

The Canadian Westinghouse Company

have the contract for this new pumping station and are supplying two 1,100 horse - power Westinghouse - Parsons steam turbines.

In the specifications, drawn up by the city engineer, it was stipulated that turbine and pump must be so constructed that either could be examined for repairs without disturbing the other half of the unit.

The pumps are of the two-stage turbine type and manufactured by the John McDougall Caledonia Iron Works of Montreal.

A striking feature of this system — which is impossible with fire engines— is the diffusion valves. In cases of large fires, and tall buildings, the two pressure stages will be operated in series; where lower pressure is desired, the speed of the unit will be reduced in proportion. By means of electrically controlled valves, a stream of water under low pressure for say the first storey of a burning building, and another stream under high pressure for the sixth, eighth or tenth storey, may be secured from the same plug by varying the pressure at the pumping station.

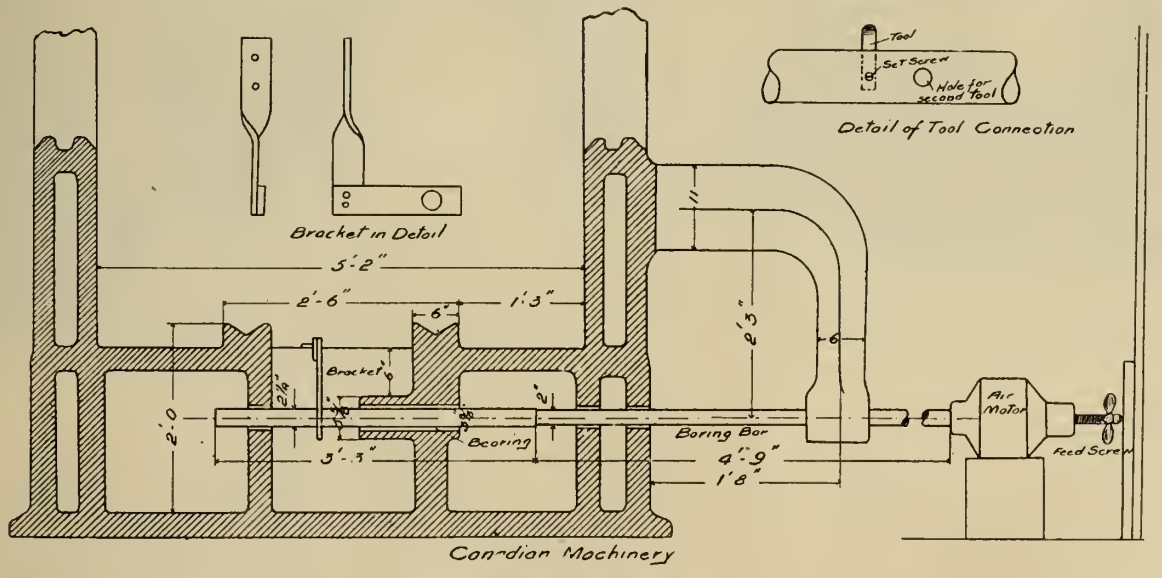
This system, as originated in Canada by the Canadian Westinghouse Company, will give Toronto the most up-to-date fire fighting apparatus in the Dominion—and will do much to prevent a repetition of the disastrous conflagration which lately destroyed a large section of the business district.

BORING OUT BEARING IN PLANER BED.

A DEVICE used for re-boring a worn bearing in a large rail-planer bed by Stanley Price in the G.T.R. shops in Toronto will be of interest to readers of Canadian Machinery.

Detail of Construction
Shipbuilding Plant.
Polson Works.

Referring to the sketch below, the pair of loose and tight pulleys are situated between the large bracket arm and the planer bed. The driving shaft ran through the holes shown in the planer bed, and through the bearing marked. On the shaft to the left of the bearing was a pinion meshing with a gear which transmitted motion to the planer table. Owing to the wear in the bearing, the pinion got out of alignment, and in consequence the teeth in the gear and pinion jammed and broke. The bearing had to be re-bored, and the method adopted is shown in the sketch. The driving mechanism was removed, and a boring-bar replaced the driving shaft as shown. The right end of the bar was supported and guided by the bearing in the bracket arm, while the other end was supported and guided by a bracket gotten up for that purpose. The bracket consists, as is shown in the sketch, of two pieces of iron bolted together, one piece being twisted around in order that it may be bolted to the bed. This bracket may easily be adjusted if, instead of circular holes as shown, slots were made in the bracket, when the bracket could be adjusted in two directions. There were receptacles in the bar for two tools, the tools being held in position by set screws, as shown in the sketch; but only one tool was used here. The boring-bar was driven by an air motor, connected as shown. This motor is of the triple oscillating cylinder type, cranks and cylinders being placed at 120 degrees. The boring-bar was fed by means of the screw in the motor. The back of the screw was jammed against a board held tightly in position, and when the motor had reached the end of the screw, the screw was screwed in again, and again blocked up. The speed of the motor was regulated by regulating air supply according to the cut taken by the tool.



Boring out Bearing on Planer Bed.

W. H. Banfield & Sons, Adelaide street, Toronto, are entering into competition with the American manufacturers on their own ground. Quite recently they have shipped a large order of dies, tools and special forms to the Siche Gas Co., Plainfield, N.J., this order having been received in competition with U. S. firms.

In this way a very complete job was effected.

"A salutation by the way costs nothing. Unlike most things that cost nothing, it is delightful to the one who receives it. A cheery good morning from a passer on a lonely road goes far toward making not only the morning, but the whole day good."

Laying Corner Stone at Niagara

ON May 9th the captains of industry who invested their money in furthering the great power scheme of the Electrical Development Co. at Niagara Falls, Ont., had the satisfaction of seeing the corner stone of the power house laid. About 100 prominent citizens of Toronto traveled to the Falls on that day and watched with interest the notable ceremony, the main stone being laid by His Honor William Mortimer Clark, Lieutenant-Governor of Ontario, and two others by Sir Henry Pellatt, president, and Mr. Frederick Nicholls, managing director, of the company. When completed this power house will be the handsomest of its kind in the world, and will be a credit not only to the company, but an ornament to the park on the Canadian side. It is built after plans submitted to the Niagara Falls Park Commission by Architect Lennox, and will contain the largest generators in the world.

The Electrical Development Co. was incorporated on the 18th of February, 1904, and on the 2nd of April of the same year work was begun on construction. The plant is situated near Tempest Point, about one-half mile above Horse Shoe Falls at the foot of the Rapids.

After the ceremony the visitors were conducted to the other power houses on the Canadian side and finally inspected the plant of the Electrical Development Co., going down and through the enormous tunnel which was built at great hazard to act as a tail race. Following this a luncheon was served at the Hospice of Mount Carmel, being presided over by Sir Henry Pellatt, and greatly enjoyed by all present. After the toast to the King had been drunk, speeches were made by the Lieut.-Governor, Mr. B. E. Walker, Sir Henry Pellatt, Mr. Frederick Nicholls, Mr. W. R. Brock, and Mayor Cutler, of Niagara Falls, N.Y. As the power bill had been introduced in the Ontario Legislature the day before, and being the most prominent topic of the day, considerable reference was made to it during the progress of the discourses. It was contended very strongly by Sir Henry Pellatt that the power bill would undoubtedly have the effect of driving away British capital and make it impossible to float further schemes on the ambitious scale carried out at the present instance.

The debt the country owed the men who had exercised faith in this development, and who had had the courage to invest their millions in it, was not forgotten, and no small tribute was paid them on this occasion.

In the course of his speech Mr. Frederick Nicholls gave probably the first public announcement of the events leading up to the undertaking. While speaking historically the facts as related demonstrated very clearly the keen foresight and judgment of the man who had conceived and carried out the early negotiations that were to culminate in this great undertaking.

OUR CONVERSATION.

"Conversation is an art worth learning. Its keynote is unselfishness. To speak without trumpeting our opinions, and to listen without interrupting, are accomplishments which a selfish person finds difficult, but which must be learned before the charm of conversation commences."

Foundry Practice

MODERN IDEAS FOR THE TRADE.

THE EFFECT OF MANGANESE ON LOW SILICON ORE*

By M. J. Walsh, Secy. Montreal Foundry Foremen's Association.

In cast iron having from 0.50 per cent. to 0.70 per cent. silicon, the addition of manganese above 1.38 per cent. gradually hardens the metal, the combined carbon and the chill increasing with the addition of manganese. When the manganese is high and the casting large enough to be gray, the fracture is open and coarse, and the graphite scales very large and crystalline. High manganese to a certain extent prevents the absorption of sulphur from coke. When manganese is below 1.30 per cent. (this percentage is only approximate and depends largely upon the percentage of silicon present; the lower the silicon, the sooner the manganese will commence hardening iron) its action is different; it softens iron, lowers the combined carbon and decreases the chill; this effect is more marked where the sulphur is high.

Manganese may be used for decreasing or increasing the chill, depending upon the nature of the mixture and the amount of manganese used. Very hot metal, stirring and skimming form sulphur reduction. Manganese can be used to advantage in low silicon and chilling iron in the following cases: In mixtures where the percentage of scrap is large and the sulphur necessarily high (this will occur in a car-wheel mixture, where usually a large portion of old metal is used) the results of this increase in manganese would be a lower sulphur, lower combined carbon, less chill and greater strength. Very often chilled plates are required, having hard chilled faces and soft backs suitable for planing. Manganese added in the right proportion will reduce the tendency to mottle and make a comparatively soft graphitic back. In all cases where chilling irons are melted and the sulphur is over 0.07 per cent. the iron can be strengthened by the use of ferro-manganese or pig iron having a high precentage of manganese. In the manufacture of large hydraulic cylinders the manganese should be kept low, as it is necessary to have a close mottled iron to withstand the pressure and prevent leakage.

Phosphorus has practically no effect upon the grade of iron as determined by fracture. As phosphorus increases total carbon decreases, and the normal amount of carbon varies from about 3.75 per cent. in normal hematites down to about 3.30 per cent. in normal Cleveland irons containing 4.5 per cent. phosphorus; that is, with an increase of 1.5 per cent. phosphorus there is an increase of 0.45 per cent. of total carbon. Phosphorus has no effect upon combined carbon, but as phosphorus increases the iron shows a lighter color, due to the phosphite of iron present.

Usual Composition of Castings.

It is by no means necessary when in any particular district, to turn out castings of the same analysis as would be done in another district where the irons within reach of the founder may be different in composition. In those districts where high phosphorus irons are cheapest, phosphorus will be found to be higher in the general output of castings than is the case where irons of a lower phosphorus content are cheaper. The same also applies to manganese.

Castings for machinery and general engineering work vary greatly in composition in different districts, but as a general rule the phosphorus averages about one per cent. Manganese usually varies from 0.3 per cent. to 1.5 per cent., but the average is about 0.7 per cent. Silicon may vary from 1.0 per cent. to 3.0 per cent. Average is 1.8 per cent. Total carbon varies to a very great extent. In some cases the total carbon is entirely in the form of graphite, in others the greater part may be combined. It may vary largely in the same casting. Sulphur usually varies from 0.03 per cent. to 0.15 per cent. In special engineering castings, where great strength is required, total carbon, manganese, silicon and phosphorus are all low usually.

For castings required to be soft and tough, hematite iron alone is used. (Low (0.027 per cent.) in phosphorus not necessarily low in manganese).

Iron for special castings is in some cases remelted once or twice before casting. This is only necessary when a higher grade of iron than is required is being used. Where reasonable care is taken in the weighing of all materials charged into the furnace, the results will be quite as regular without this remelting. The effect of remelting in the cupola is equivalent to lowering the grade. Usually silicon is decreased 0.2 per cent. to 0.3 per cent. Sulphur usually increases to the extent of 0.02 per cent. to 0.04 per cent. About 25 per cent. of the manganese is lost. Total carbon increases or decreases according to the amount present, whether below or above the normal.

Phosphorus.

A very slight amount of phosphorus is absorbed from fuel by iron in melting. It is practically a constant quantity, the small increase being proportionate to the amount of phosphorus in the fuel.

Manganese loses in passing through a cupola. Its action is that of a protector from oxidation, and the amount lost in passing through depends upon the amount of blast and also upon the percentage of sulphur in the fuel. The greater the amount of air forced into the molten metal the more manganese is lost as an oxide. The greater the percentage of sulphur in the fuel the greater will be the percentage of manganese passing into the slag as a sulphide. Manganese is not united with iron as a compound, it is rather alloyed with it, having practically no affinity for the iron.

Carbon.

Iron may lose or gain carbon in melting. This is governed by the composition of the iron and the conditions or method of melting. An iron while passing down a cupola has a portion of its carbon burnt off, the quantity depending upon the amount of blast and the time which the iron takes to pass through the zone of the cupola where the oxidizing influences are at work. After having a portion of its carbon removed the molten iron comes into contact with the incandescent coke in the bed, and from this it absorbs carbon. The hotter the iron the larger the amount of fuel, and the longer the iron remains in contact with this fuel the more carbon it will absorb. If the amount of fuel is sufficient, the iron may absorb more carbon than it loses in passing the tuyeres. If, however, the blast be heavy, and the ratio of fuel to iron small, the iron will lose more carbon in passing through the oxidizing zone than it can possibly pick up from the bed. Melting with high blast and low percentage of coke will cause a loss of carbon while low blast and high percentage of coke will cause a gain.

THE ONTARIO POWER BILL PASSED.

THE much talked of power bill of the Ontario Legislature has become law. It has been denounced by some as an attempt at socialism and railed at by others as a weak effort to bring into line the existing power companies at Niagara. These are extreme views and in no way reflect the judgment of the great majority of interested parties—and the number interested includes every thinking man in the province. In the main the bill is a compromise between the natural rights of the people of the province and the vested rights of the capitalists who have undertaken the enormous developments. While the question is being discussed and thought of in connection with Niagara and the western peninsula of Ontario alone, since it is there the test of its feasibility will be made, the entire province will be equally affected, as the bill applies to all water power.

Ontario's industrial future unquestionably hangs in the balance with the decision regarding the disposal of her water powers and a reasonable decision as regards permanency and stability to manufacture and the promotion of industry has been given.

The first clause of the bill provides that the Government shall appoint a hydro-electric power commission, one of the three members of which shall be a Cabinet minister, the province to pay the salaries of the commission and for electrical and financial experts. The commission is to supply estimates to any municipality desirous of securing electric power from any water fall, and this estimate shall be furnished in detail. If the municipality determines that the price quoted is reasonable and is willing to enter into contract for a block of power the matter shall be submitted to the electors by the municipal council, and if the vote be negative negotiations will end. If the electors agree to the necessary expenditure the council is empowered to make the contract for the power required. Transmission lines, transformers, and the necessary equipment will be supplied by the commission on the credit of the province, this expenditure to be provided by the municipality by its paying the commission 4 per cent. interest annually, a sinking fund sufficient to wipe out the indebtedness in thirty years and an annual maintenance or renewal charge on the plant. The commission shall fix the rates and the consumers shall pay the municipality for power. In addition to municipalities the commission will have the power to supply electric energy to any railway or private company distributing electricity. Thus if a town decline to take up the matter with the commission private individuals in the town might do so. The clause giving the commission power to demand electric energy from the power companies on peril of the expropriation of the work has aroused the greatest discussion. This as well as the power to expropriate transmission lines insures finally the safeguarding against high rates, either for energy at the water fall or an unreasonable price for its transmission.

In this there is evidently no attempt on the part of the Government to force the existing developing companies to part with their property at a loss or to generate electricity at a price that will not be fair to all concerned. What the bill does aim at, and which if carried out it will surely secure, is that the manufacturing interests of the country will be able to secure power at a rate to enable them to make the Province of Ontario a hive of industrial activity. In the carrying out of this no British or other foreign capital should be frightened away. The matter should be looked upon as a partnership between the people of the province and the developing companies, with the Government commission as managing directors of the agreement.

THE FIELD FOR PRODUCER GAS.

IN Canada, and especially in Ontario, at present the one power topic is electric power. It is being discussed privately, publicly, in the press and in the Legislature. But while this is so, there is another form of power which will have no mean future in Canada, even as compared with electric power. This is producer gas. Of late years the attention of engineers and manufacturers in Canada has been more and more directed to producer gas as an economical and efficient form of power, with the result that experimental work upon producer gas plants was started and companies formed to manufacture them. Thus far any gas plants that have been installed in Canada are European design, and probably any that will be developed within the next few years will be after the style of some of the English gas plants. Already several firms have been organized and are manufacturing, or making arrangements to manufacture, producer gas plants in Canada either under English, German or United States patents. Not only are manufactories starting up, but consulting engineers are paying considerable attention to the matter; some even making a specialty of gas plants.

In the face of this evidence a good future for producer gas in Canada seems assured, but it is more the inherent qualifications of producer gas itself as a source of power that leads one to predict great things for it. The prime question in regard to power is its comparative cost, and in this respect it would appear that producer gas is exceptionally satisfactory. Tests made upon gas engines developed by English manufacturers especially to operate upon producer gas showed as low a coal consumption as 0.83 pounds of Scotch anthracite pea coal per brake horse-power, engine running under full load, and 0.91 pounds per brake horse-power, engine running under half load. Producer gas plants have by no means reached perfection, nor have gas engines, and even better economy than this may be expected with the further improvement of the plant and engines. Another important point in a power question is the reliability of the power plant and cost of maintenance. In this respect also the producer gas plant appears to give satisfaction. Of course the gas plant has not reached the state of perfection that the steam plant has, and consequently it is possible for something to go wrong, for which there is no "rule of thumb" remedy; and while expert labor is not required to look after the plant, it should not be left in charge of anyone not having knowledge of the difficulties to be met in the operation of it.

Experiments have shown that the gas plant can be brought to full working load in a remarkably short time. Starting with the producer cold and empty, a gas producer made by an English firm attained under full working load in less than 15 minutes. This was under test, and it is not to be expected that in actual practice this could be done, but this gives an idea of the qualifications of the gas plant in this respect.

PROBLEM OF THE LARGE GAS ENGINE.

WHILE only rich coal gas was used in gas engines, their field of usefulness seemed limited to the smaller sizes, since only then could they compete in economy with the steam engine. With the utilization of cheap forms of gas, such as blast furnace and producer gas, as a fuel in internal combustion motors the gas engine industry started a revolutionary movement. This commenced in Germany and Belgium and spread to other European countries and England. Quite recently manufacturers in the United States followed Germany's lead, and now there are firms in Canada prepared to build these large gas engines when the occasion demands. With the development of these immense units in the gas engine line many difficulties were met with by the designers and manufacturers never thought of in the small units; and, indeed, such radical changes have been made in some of the large gas engines during their development as to make them scarcely recognizable as originating from the ordinary small Otto cycle gas engine.

There are two distinct styles of large gas engines, those operating upon the Otto cycle and those operating upon what is commonly known as the two-cycle. The attempt was made to develop the engine by keeping to a single cylinder and increasing its size. This style showed economy in both gas consumption and floor space, but owing to the difficulty of balancing the moving parts in the large engines and other reasons it was found advisable to create large units by combining several cylinders in various arrangements. It was also found advisable to make the engine double acting instead of single and to place cylinders in tandem, because of the finer speed regulation obtainable. It being desired to adapt the gas engine to the operation of electric dynamos, minute regulation of speed under varying load was required, and this led to the development of efficient governing mechanisms, the most efficient being probably the Mees system used on some French and German engines.

A few of the fundamental difficulties met with in the development of these large engines were in connection with the design of the frame, in the construction and operation of the valves and valve gear, in the cooling of the parts in contact with the hot gases, in the circulation of the cooling water and in the starting of the engine. Most of the firms developing these engines had had previous experience in the construction of large steam engines, and this was of value in designing the gas engine frames. The valves are mechanically operated, cone seated, poppet valves. A question not yet definitely decided is whether it is not more advisable to have the valve gear operated by eccentric motion instead of cam and roller mechanism. In these large engines it is essential that all parts coming in contact with the hot gases should be water cooled and for that reason the cylinders, the pistons, the piston rods, the stuffing boxes and the valves must be water jacketed. On the large engines the circulating pumps are driven from the main shaft of the engine and not from the valve shaft, but it is now becoming common practice to drive the pump by electric motor. There are two common methods of starting the engines. One is to use one cylinder of the engine as a compressed air motor, until a charge has been ignited in the other cylinder or cylinders; but the most popular method is to start the engine with an electric motor, a pinion on the motor shaft meshing with gear teeth on the fly wheel.

FEW MANUFACTURERS IN PARLIAMENT.

NO body of equal importance and representing equal interests in the country is less represented in Parliament than our manufacturers. They are carrying on great industries, employing thousands of hands and building up the country in a stable manner, and yet in the great body of parliamentarians you will find them but very slightly represented. The main reason of this may be that those at the head of our industries are too engrossed to take an active part in the country's affairs. What we would like to see would be a larger sprinkling of manufacturers both in the Dominion and Provincial Legislatures. Their influence could not fail to be for good, and it is hoped that more manufacturers may decide to enter public life and help in a broader measure than they may even now be doing to advance the industrial interests of the Dominion.

UNIVERSITY AUTHORITIES OBJECT.

IN an editorial entitled "Useless Energy for Technical Students," appearing in last issue of Canadian Machinery, reference was made to the loose methods in vogue in the engineering department in one of our Canadian universities. Both the authorities of McGill University and Queen's took exception to this on the ground that it might refer to them, but it did not. As this places the matter on the head of the one large remaining university with a science department we hope the editorial in question will have the desired effect and that no more complaint will be possible regarding lax methods of instruction.

Milling Cutters; How They are Made Used and Abused.

By John Edgar.

ARTICLE II.

IN selecting cutters for any particular job there are several points to which we must pay special attention. The most important of these is the grade of finish the work requires.

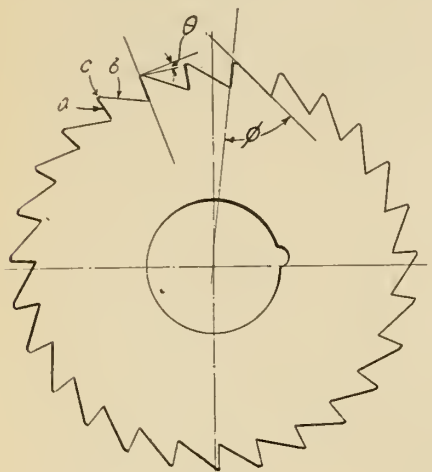

Fig 5

On this one point hinges whether the equipment will cost much or little. If the finish is of a coarse character the cutters may be made more cheaply, not so much by reason of difference in quality but rather in quantity, since the rough work would require but one set of cutters because but one cut would be necessary, whereas should the quality of work be such that the range between the limits set for accuracy be small we would require two sets of cutters, one for removing the bulk of the stock and the other for finishing the piece to size.

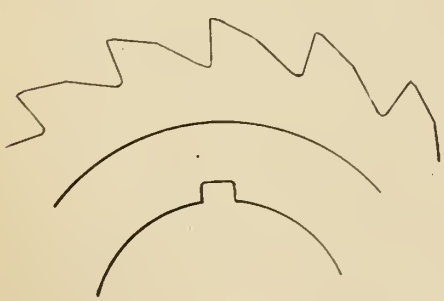

Fig 6

Much depends, too, on the facilities at hand for milling the work. Some jobs may be more easily worked on a vertical milling machine, but there may be no such machine at hand, or at least it may not be open to receive the work as we want it. In milling a large surface we have two methods to resort to in most cases. These are, first, the use of a horizontal spindle machine, which will require a set of very expensive cutters, while for a second method we have the vertical machine, which requires a cutter of much less expensive make. We may resort to the same style cutter that would be used in a vertical spindle machine when we have none but horizontal machines at hand, but the setting of the work may take a very complicated form in trying to use such a cutter for this purpose.

In selecting cutters it is important to keep the diameters down as small as possible. This is not only important from the standpoint of first cost, but from the time saved in the feed, especially so where short cuts are made, and from the economy of power required for a given amount of chips removed.

In making up gang of cutters it should be made a point to have the cutters as near the same diameter as possible because there are speeds at which cutters work best, and a variation either side of this speed produces poor results. But where it is impossible to overcome this fault the large cutters should be speeded up to the limit so that the smaller cutters may come as near as possible to the ideal speed, otherwise they will tear the work, leaving a ragged surface. The slower a cutter runs the greater should be the number of teeth in proportion to the diameter.

All these things are dependent on the work in hand, and cannot be dealt with in a general manner.

Explanation of Terms.

Before we enter into the question of the construction of the cutter a brief description of some of the terms that are used in connection with them will not be out of order. In figure 5 is shown an end view of a milling cutter. The different parts of the tooth are lettered, (a) being the face of the tooth, (b) the back of the tooth, (c) being the land, (ϕ) being the angle of the tooth, (θ) the angle of clearance, The angle

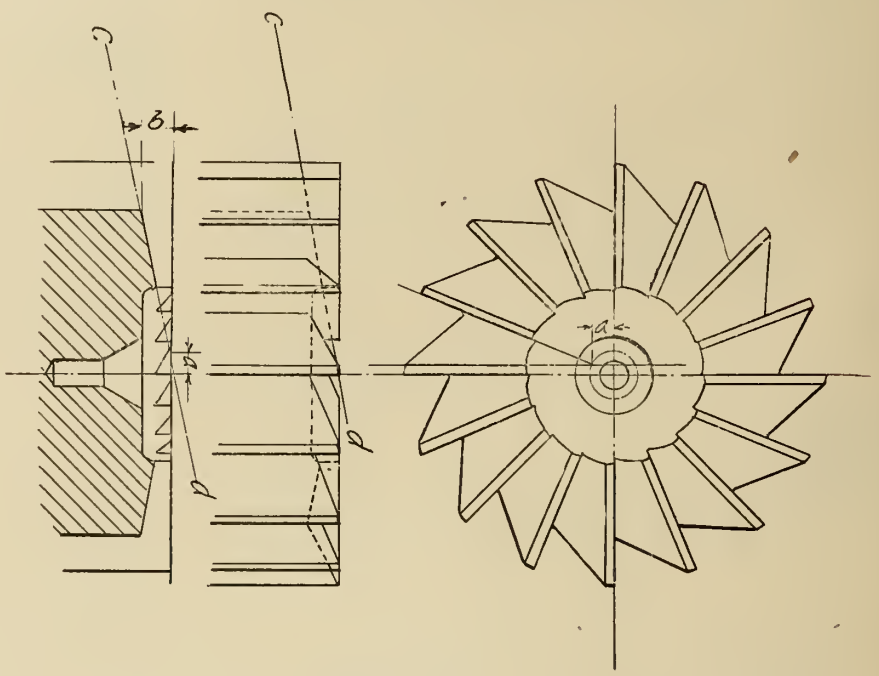

Fig 7

of tooth (ϕ) is usually made about 50 degrees, but of course varies, as it would be impractical to make a different cutter for each diameter cutter to be cut. The angle of clearance varies from 3 to 9 degrees, the larger value being used on roughing cutters. The land (c) is generally made about 1-32 or 3-64 of an inch wide at the first grinding.

Number of Teeth.

The number of teeth in a cutter has been for some time a bone of contention among different authorities, but the average values of various manufactures of cutters on this continent are those given in the table.

TABLE I.

Diameter of Cutter.	Number of Teeth.	Diameter of Cutter	Number of Teeth.
½ in.	6	2½ in.	21
¾ "	8	3 "	24
1 "	12	3½ "	26
1¼ "	14	4 "	28
1½ "	16	5 "	30
2 "	18	6 "	32

While the above figures are the general practice, it will be found to advantage in the cases of cutters of 3 in. and over, when used on cast iron, to make them with fewer teeth, especially so for roughing work. When extra heavy work is to be done with a cutter the teeth are sometimes made the shape as those shown in Fig. 6, which are much stronger than the regular single cut

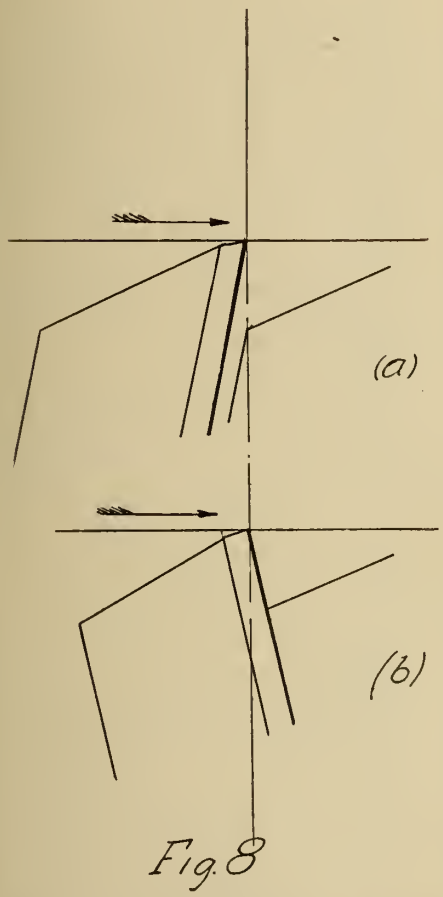

Fig. 8

teeth. It is important that all cutters be made with a fillet of considerable size at the root of the tooth as this is an exceedingly weak point, and if a fillet is not allowed the cutter is liable to crack in hardening.

Finding Angle.

In designing end and side milling cutters it is necessary that the land on the side and end teeth be of uniform width from the circumference toward the centre. This is accomplished by making the cut at an angle as shown in Fig. 7. The proper angle for this cut may be found by laying out the cutter as shown. The radial line adjacent to the face of the tooth is produced to intersect the line adjacent to the back of the land. At this point of intersection the cut line (cd) should intersect the plane of the end teeth. The depth of the cut (b) determines the angle of this line.

Some Requirements.

The majority of end mills are made with spiral teeth. For ordinary purposes this spiral should be of the same hand as the cutter, that is, a right hand cutter should be cut on a right hand spiral, but for die sinking and on similar work, where a line is used as a guide, the spiral should be opposite to the cutter, that is, a right hand cutter should be cut with a left hand spiral, since the direction of the spiral will then be against the face of the work, forcing the metal away from it, leaving no burr to cover the line, as would be the case where the conditions are different. Where milling is to be done with the end teeth the former is the way they should be cut, as is easily seen from Fig. 8. The case (a) has a good front rake, while (b) has a back or negative rake, which would produce a scraping action instead of the clean cutting action that is desired.

Large Millers.

When cutters reach the 6 inches in diameter it is good practice to make them with inserted teeth. This is done as a matter of economy, both for reasons of first cost and subsequent maintenance. There are several ways of holding the teeth, some of which are shown in Fig. 9. That at (a) is the simplest and answers the purpose very well. As will be seen the taper pin is driven into the slot, which causes some expansion, binding the cutter blade securely in its seat. When new ones are to be put in place or the old ones adjusted it may be accomplished by merely removing the taper pin. What could be simpler? The method shown at (b) is another good way to accomplish the desired result. The taper bushing is drawn down into the taper seat, and bearing on the blade causes it to be secured to its seat in a rigid manner. Another simple way of holding the blades is by the aid of a gib such as shown at (c). The above are three widely different ways of doing the same thing, and represent the practice of as many different cutter manufacturers.

It is apparent that owing to their construction inserted tooth cutters must have less teeth in proportion to their diameters than the solid cutters. The table below gives the general practice in regard to this point.

Inserted Tooth Cutters.

TABLE II.

Diameter of Cutter.	Number of Teeth.	Diameter of Cutter.	Number of Teeth.
6 in.	12	10	20
7 "	14	12	24
8 "	16	14	28
9 "	18	16	32

These figures give as the pitch of the teeth 1.5-2 inches, which is ample for the designs given, and where the bodies are made of steel may be somewhat shorter, that is, the number of teeth may be increased.

When it is desired to have the cutting faces of inserted tooth mills on a spiral we must proceed as follows: The blanks are first slotted out on an angle, which

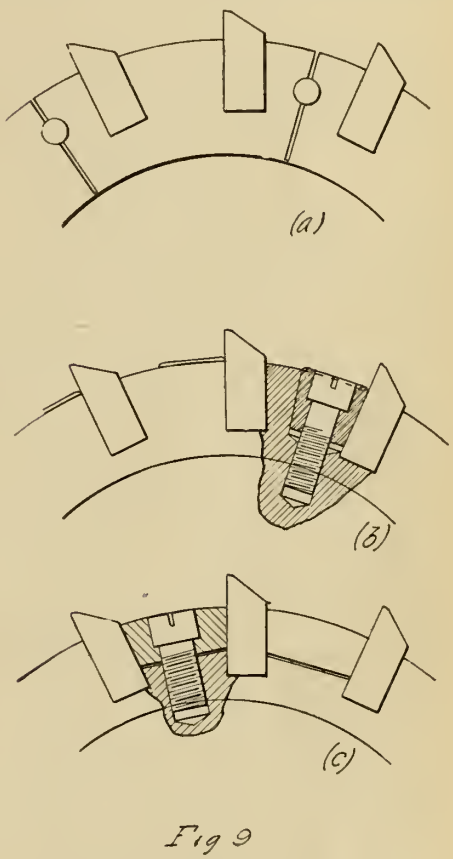

Fig 9

is usually made about 12 degrees, the width of the slot and the teeth being slightly wider than when the teeth are set parallel to the axis of the cutter, the teeth are then set in and secured, and a spiral cut is then taken over the face as in the ordinary solid spiral milling cutter. If the angle is made much more than 12 degrees the twist in the spiral cut will be more, and consequently the ends of the tooth will be much thinner.

In the next article we shall take up the setting of the machine and the different methods used in making the cutter.

The Uses of Electricity in the Modern Shop*

By Galvin W. Rice, Cousulting Engineer of the New York Office of the General Electric Company.

THIS is a large subject, too varied to be treated in an evening, much less in the few minutes allotted. However there is an opportunity to bring out a few points. First of all, I wish to emphasize the engineering side, which in reality is the foundation of the successful application of electricity, or of any of the forces of nature to the uses of man. Second, make a servant of the force of nature rather than permit it to be your master, whether it be electricity or gravitation, and whether the application can best be made directly or through a hydraulic or a pneumatic medium.

The intent of these two features of my remarks, namely, the engineering side and the attitude of mind which makes it possible for one to utilize any force according as it is the most available, will be better appreciated as I progress. I shall be satisfied if these two things are all you remember of my remarks.

We are just now hearing in Germany and other foreign countries of the American evil; but may we not as truthfully beware of the German evil, with their groundwork of technical training? One obtains at a technical school fair instruction in the laws of electricity and an opportunity at least to become acquainted with electrical machinery, but this is not sufficient. In fact, it is the absence of the above important factors which is the reason for our not attaining even greater progress. You will have no failures in applications if the engineering side is first thoroughly studied, and then the apparatus intelligently installed.

The first question to decide is, what is the length of time for which such a plant will be used after constructed and how can it later be increased? Always have in mind what you may be required to do when successful, and when the improvements which you have instituted shall have produced the expected increased output.

Value of Motor Drive.

Electricity is now almost universally employed in some form or other in industrial work. At another place I am speaking of the economies which are secured by means of electric drive over that by belts and shafts. In this connection it is well to emphasize the improvement in general lighting due to the absence of belts and the convenience of direct connected units, which has a distinct commercial value. Another important point is in the saving of the capacity of the prime mover on account of the fact that almost never are all the motors required to operate at full load at any one moment. Consequently, it is good engineering to install the generator of perhaps not more than two-thirds of the capacity of the connected load, but this relation varies according to the industry.

Another important advantage of electric drive is in the uniformity of speed which may be secured, which not only improves the quality of the product but also the quantity, this latter feature being due both to the uniform speed and to the fact that there are fewer defects in the output. This is peculiarly true of all weaving, whether of cotton, wool or silk, and in the spinning of the same, also of all paper manufacture. Expert may detect particular machine.

I am aware, from the letter of your chairman, that there is represented here this evening the greatest variety of industries, but I feel safe in saying that there is almost no industry which may not be benefitted by the application of electricity in some form. it may be in an addition to an old mill, if not complete equipment of a new mill. The prime mover may be steam, water or gas. Motors may be belted or direct connected. There is the greatest possible range of speed, secured economically, quickly, and conveniently. All the machinery may be electrically driven or only a part. Portions of a plant or whole buildings may be electrically driven while other portions may continue to be driven as they are now; or it may be best to install a separate steam plant, keeping in mind always to do that which is best after having considered every point of view; some of the apparatus may be electrically operated directly, or through some other medium. For example, elevators may have a motor direct connected to the worm gear, or the motors may operate pumps on enclosed tank system which in turn actuate the elevator. The combination of electrical and mechanical methods is always considered.

In passing, I wish to speak of the nicety to which starting and controlling devices have been elaborated, so that there are to-day several large and successful firms engaged solely in the business of designing and building such apparatus.

These are so arranged that they provide for an excess pressure, or for no pressure, and also for overload. They are fool proof, so that any attendant, no matter how youthful or inexperienced, may operate them. An instance of this is in the elevated and subway roads in New York City, where a multiple unit control of motor cars has been substituted for steam locomotives. A large number of steam engineers would otherwise have been thrown out of employment, but instead gradually were instructed in the use of the electric controller so that they have resumed their previous positions, only now being entitled motormen instead of engineers.

Motors may be located on the ceiling, as well as on the floor or on the wall. Self-oiling bearings are universal, and although the best design of direct current motors require little or no attention of the brushes on the commutator, with alternating current motors even this is done away with, so that the minimum of attention is required. Remote control starting devices are installed whenever the motor is inaccessible or otherwise desirable.

For miscellaneous tool work motors may be combined with a portion of the frame, and in some cases entirely housed in the pedestal.

The ability to secure variable speed is now very great. This is particularly necessary in the case of newspaper printing and cloth printing works. The very slow speed, about one-tenth the full speed, is required for the making ready, and there is a slow running speed when time is necessary for the impression, a medium speed for regular work, and a maximum speed for rush work.

Formerly it was quite common to vary the pressure by interposing a resistance in the armature circuit, which in turn varied the speed. This is always an uneconomical method, as practically the same power is consumed regardless of the speed, and the speed was not always steady, and the variation of the same was always within the normal speed of the motor. Now, however, motors are designed for variable speed by changing the field strength. This is quite economical, and the consumption of current is practically proportional to the work done. With this method a range of speed from even 5 to 1 is possible.

The control apparatus for motors is usually extremely simple. For more elaborate work, and at the same time economical operation, there are several systems where a multiple voltage or variable voltage is secured by one or more extra generators.

I have just touched on some of the general phases of the application of electricity. But I want to take up also briefly the future, and the opportunities for everyone within hearing to study the

*Remarks, on Manufacturers' Day, at Niagara Falls, Ont., before the Boards-of-Trade of the Canadian and United States Cities of Niagara Falls.

possibilities in electro-chemical and electro-metallurgical processes.

Electrolytic Possibilities.

It is in this field that there is the greatest reward. Think of the already many successful processes here at the Falls; and they are but a fraction of the possibilities. Take, for instance, aluminum as an example, and all the benefits and possibilities of an electrical process for its manufacture. Fifteen years ago the amount of aluminum made in the United States was 61,000 pounds, valued at about $1.00 per pound; last year the output was 9,000,000 pounds, valued at less than 30c. per pound. Practically all of the copper of the United States is electrolytically refined, with the exception of some ore from the Lake Superior district, but even a portion of it is refined in the works of the Calumet & Hecla Co. located in Buffalo. Some of the products which are, or easily can be, made with electric power are chlorine, bleaching powder, potassium chlorate, sodium chlorate, carborundum, aluminum, artificial graphite, sodium calcium, sodium peroxide, sodium oxone brand, calcium carbide, caustic soda, sodium hypochlorate, barium peroxide, potassium per-carbonate, ferro-titanium, and many ferro alloys. But if you should ask which are the materials to select I say the piration of nitrogen for nitrate or fertilizer and more particularly recommend those which are most used, iron and steel.

Electric Smelting.

You have this much to start on. It is successfully and commercially being manufactured in Sweden, Italy and France. Why not here? You of Canada should be particularly interested, as has been pointed out only a month ago by your able Superintendent of Mines, Dr. Haanel, before the Canadian Club, of Toronto.

He emphasized the favorable conditions in Canada due to the peculiar action of nature in placing large ore deposits in Alberta, Ontario, Saskatchewan and Quebec, but giving you no coal there. You are obliged to go to the coast in either direction for coal, but large water powers are at hand waiting to be developed.

Here is where electricity solves the problem. There is almost no distance to which electricity may not be transmitted. The longest on this continent, and perhaps in the world, is in California, from the Sierras to San Francisco, a distance of upwards of 220 miles, with a pressure of 60,000 volts or more in the Bay Counties System. But it is not necessary to consider these enormous distances, as in most all cases water powers are possible of development, which are nearer by. Canada is most peculiarly and favorably situated in this respect. You are typical of the man whom the Lord gave ten talents. One says there are difficulties. Of course there are. But who cannot overcome them? Watch San Francisco rise.

Carbon for reduction is, however, necessary, and it will be necessary as a part of the problem to develop a process with wood, or from coke made from peat of which there are ample deposits in Ontario and Quebec.

One of the interesting discoveries is that the chief ore in Canada is magnetite, much of which contains too much sulphur for successful smelting in the blast furnace; but on the other hand can be handled successfully by the electric furnace. All of this has been recently determined anew at Sault Ste. Marie under the direction of Dr. Paul Heroult.

The success of this process has already been known, having been given in the report of Dr. Haanel in 1904, which showed that even pig iron could be produced on a commercial scale and compete with the blast furnace, if electric power could be secured as low as ten dollars per H.P. year and coke at $7.00 per ton. These results, however, were determined from furnaces not designed particularly for the work, and since it has been shown that they could be improved upon with a specially designed furnace.

The Lake Superior Power Co. has recently furnished a building and the use of 300 H.P. gratis, and the Canadian Government has co-operated, appropriating $15,000 for tests. These tests on the Canadian ores commenced the middle of this last February, and in the month following about 150 casts were made, from which upwards of 55 tons of pig iron were obtained.

It was determined in these tests that both charcoal and peat coke could be substituted for coke as a reducing agent without being briquetted with the ore. I beg to quote from the concluding paragraphs of Dr. Haanel's address:

"The Government has furnished you with facts on which to base a sound judgment as to the feasibility of commercially engaging in the manufacture of pig iron by the electric process; with that its duty to the nation is done, and it remains with you business men to apply, perfect and profit."

The amount of current per ton of pig produced is about 83 H.P. days per ton of 2,000 pounds. The relation of electric power to the cost of production and the relative importance of the several iron products are as follows:

In the Kjellin process for the manufacture of crucible steel the cost of electrical energy for producing 1,000 kilograms of ingots on a basis of $10 per H.P. year, is $1.48, and the total cost is $37.48, which shows that the cost of electrical energy is comparatively small in this high-class material. Crucible steel made by this process is equal in all respects to the best Sheffield crucible steel, and can be produced at a cost considerably less.

In the Heroult process, which has just been repeated at the Sault Ste. Marie, the fuel consumed in an ordinary Siemens furnace would vary from 1,000 pounds to 1,800 pounds of good slack coal per ton of steel produced. Such coal would probably cost $5.00 to $5.50 per ton of 2,000 pounds in Canada, let us assume 1,200 pounds per ton, would mean, say, $3.00 per ton of steel. The cost of electrical energy at $10 per electrical H.P. year would be $1.53, the electrodes, etc., are estimated at 20c., making a total of $1.73 as against $3.00 for the cost of coal.

Everyone coming to the Falls is impressed with its indescribable grandeur, and considers it an event of his life to have been permitted to witness it. But I am more impressed with the thought of how we may use the benefits that God has lavished upon us.

Availability of Coal.

The criterion, of course, is coal. That is the source of the bulk of our energy that is industrially employed. In the United States from coal and other fuels upwards of nine million horse power is developed for the operation of various plants. Therefore, at your feet you have, by the most conservative calculation, one-fourth of the power of all the steam plants of the United States.

Elsewhere I have spoken of the economy of electric drive, which will now be more apparent in this connection. The efficiency of an ordinary steam driven engine and shaft transmitting power by belts is from 75 per cent. to 50 per cent., and more often the latter, between the brake H.P. of the engine and the work done on the machines. Often I have indicated an engine in a plant at noon-time, when absolutely no work was being done other than driving the belts and shafting, and I have found the load on the engine to be 50 per cent. of that when the shop was running full. There we have a spectacle of the wasteful use of coal. To develop water powers, therefore, is to save coal twice over.

It may not be out of place to mention that we are not always to have coal; its supply is not exhaustless. I do not want to be considered as making wild statements, but I will give a few facts and state the authorities.

In the annual statement of the House of Commons by the Board of Trade is given the average value per ton of the coal mined from the year 1883 to the present, from which I have summarized as follows: In the United Kingdom the price has nearly doubled; but in the case of the English colonies it has decreased, with the exception of Canada, India, and

Australia; however, the relative production of the colonies to the British Isles is less than 1 per cent.; in Canada, India and Australia the production is only 3 per cent. of that of the British Isles. So it may generally be stated that in the British Empire the price of coal is steadily increasing. With all the rest of the world, with two exceptions, it is also increasing, in every case by 10 per cent. and in some 50 per cent.

The two exceptions are Japan and the United States. Now, what relation does the production of Japan have to that of the world? Less than 1 per cent. The United States, on the other hand, produces over one-third of the world's supply. The United States, then, is the only important exception to the steady increase of the price of coal.

The industrial and economical importance to you of these Falls cannot be over-estimated. The opportunity to utilize this magnificent power and the various powers throughout Canada is in the application of electricity. The one of you doing the most good in this world is the one who builds up. The use of coal is reducing the world's supply, which can not be renewed, but to develop water powers is to conserve the supply.

TESTS ON TEMPERING TOOL STEEL.

A Report on the Preliminary Tests made on the Schenker Process of Tempering Tool Steel.
By Prof. H. M. Jaquays.

THE objects of the tests made were: (a) To compare the performance of tool steel when tempered (1) by the Schenker process, and (2) in the manner recommended by the maker. (b) To compare the performance of ordinary low-priced tool steel, tempered by the Schenker process with some high-priced, high-speed tool steel. The steels tested were: (1) Parkes tool steel, 16c. per lb., 1 in. x $\frac{5}{8}$ in. section. (2) Parkes tool steel, 8c. per lb., 1 in. x $\frac{5}{8}$ in. section. (3) Firth tool steel, 15c. per lb., 1 in. x $\frac{5}{8}$ in. section.

Pieces about 15 in. long were obtained of the above, and from each piece two tools were made. One of these was tempered in the manner recommended by the maker, and the other by the Schenker process. The tools were all similar in design.

Manner of Making Tests.

All tests, except those made to compare hardness, were made on a lathe. The material used for turning was, in most tests, cast steel—an old roll and very hard.

Speed variation was effected by cone pulleys, consequently it was impossible to keep the cutting speed constant, as the diameter of the cast steel roll decreased. Every precaution, however, was taken to keep the cut, traverse and speed as uniform as possible in those tests which are comparable.

Results of Tests.

Firth Steel—Material tested, cast steel.	Tempered as per maker's instructions.	Tempered in Schenker process
Trial number	1	2
Depth of cut (inches)	1-8	1-8
Traverse "	0.0164	0.0164
Mean speed of cutting (ft. per min.)	38.5	35.5
Duration of trial (min.)	71	115
Amount of material removed (cu. in.)	67.2	160
Rate of removing material (cu. in. per hour)	56.8	52.5

The results of the tests of trials 1 and 2 are shown in the foregoing table.

In the above trials (1 and 2) both tools were used until they failed. The tools were then re-ground but not re-tempered, and tested with the following results. Trials 3 and 4:

Firth Steel Same tool as in trials 1 and 2 Re-ground but not re tempered. Material tested, cast steel.	Tempered as per maker's instructions.	Tempered in Schenker process
Trial number	3	4
Depth of cut (inches)	1-16	1-16
Traverse "	0.0164	0.0164
Mean speed of cutting (ft. per min.)	35	32
Duration of trial (min.)	85	108
Amount of material removed (cu. in.)	34.5	42.7
Rate of removing material (cu. in. per hour)	25.9	23.7

These trials show that the tool tempered by the Schenker process removed, in trials 1 and 2, 1.49 times, and in trials 3 and 4 1.24 times, as much material as was removed by the tool tempered according to the maker's instructions. Trials 5 and 6:

Parkes Steel—16c. per pound. Material tested cast steel.	Tempered as per maker's instructions.	Tempered in Schenker process
Trial number	5	6
Depth of cut (inches)	1-16	1-16
Traverse "	0.0164	0.0164
Mean speed of cutting (ft. per min.)	45	43
Duration of trial (min.)	64	170
Amount of material removed (cu. in.)	35.4	78.5
Rate of removing material (cu. in. per hour)	33.2	31.8

At the end of trial 5 the tool tempered in the manner recommended by the maker failed. At the end of trial 6 an attempt was made to run at a speed of 65 ft. per min., but tool failed.

Trials 7 and 8:

Parkes Steel—Same tools as used in trials 5 and 6. Re-ground, but not re-tempered Material tested, cast iron.	Tempered as per maker's instructions.	Tempered in Schenker process
Trial number	7	8
Depth of cut (inches)	1-8	1-8
Traverse "	0.017	0.017
Mean speed of cutting (ft. per min.)	60	60
Duration of trial (min.)	3.7	10.5
Amount of material removed (cu. in.)	5.56	16
Rate of removing material (cu. in. per hour)	91.8	91.8

These trials show that the tool tempered by the Schenker process removed, in trials 5 and 6, 2.22 times, and in trials 7 and 8 2.86 times as much material as was removed by the tool tempered in accordance with the maker's instructions. In trials 9 and 10 Parkes steel, eight cents per pound, was used. The tools, which had been previously used until they failed, were re-ground but not re-tempered. Trials 9 and 10:

Parkes Steel—8 cents per pound. Tools re-ground, but not re-tempered. Material used, cast steel.	Tempered as per maker's instructions.	Tempered in Schenker process
Trial number	9	10
Depth of cut (inches)	1-16	1-16
Traverse "	0.0164	0.0164
Mean speed of cutting (ft. per min.)	46	43
Duration of trial (min.)	6.1	33
Amount of material removed (cu. in.)	3.44	17-5
Rate of removing material (cu. in. per hour)	33 9	31.8

In trial 10 the speed at the beginning was 46 ft. per min., but as the diameter of the piece being turned decreased the speed, at the end of the trial was 40 ft. per min. These trials show that the tools tempered by the Schenker process removed 5.1 times as much material as the tool tempered in the ordinary manner. At the end of trials 9 and 10 both tools failed.

Hardness Tests.

Tests were made to compare the hardness of the different tools with the following results. The tests were made on a piece of tempered tool steel. Sample I, steel tempered as per maker's directions, failed to make any impression on the material. Sample II, air hardened, cut material slightly. No.I, tempered by the Schenker process, cut materials much more easily than did the No. II. The No. I tool, tempered by the Schenker process, was undoubtedly harder than the other tools. The tests for hardness were made on a shaper running at a very slow speed.

No cheating nor bargaining will ever get a single thing out of nature's "establishment" at half price. Do we want to be strong?—we must work. To be hungry?—we must starve. To be happy?—we must be kind. To be wise?—we must look and think.—Ruskin.

Producer Gas.*

By W. H. Ellis, M A., M B.

AMONG the competing fuels of to-day the gases play an important part, and the rapid growth of industrial enterprises in those districts where natural gas occurs may be adduced in support of this statement. In less favored regions, coal or oil gases which have large calorific values may be employed, but unfortunately their high cost has prevented any widespread use.

In general it may be said that only two varieties of this class of fuels are of importance for the production of power, viz., blast furnace gas and "producer" gas. The former, which results from the regular operation of the iron blast furnace, was formerly used simply for heating purposes, but it is now employed largely in driving the blowing engines; it is obvious that this gas is not available for the manufacturer at large, and hence it will not be further discussed in this paper.

"Producer" gas, which has become very important commercially, can be manufactured, on the other hand, in small or large quantities, and necessitates the use only of a small and compact plant. The methods of production vary according to the amounts of gas required, but the general process may be described as follows: Air, or air and steam, are passed through a red-hot body of fuel contained in a suitable brick-lined furnace, and the fuel and air are intentionally only half burned. This effect is favored (1) by using a thick bed of fuel; (2) by keeping the temperature below a certain limit (by varying the amount of steam) and (3) by supplying only enough air to allow partial combustion.

It will be here observed once more that this closely resembles very bad firing as sometimes conducted under power boilers. Indeed, the point has been well illustrated by the remark on a case of very bad firing, that the owner was running a gas producer and not burning the producer gas.

In the typical gas generator the process is usually continuous, fuel being fed in as needed, while the steam and air blasts are introduced simultaneously. Any class of fuel may be employed. If, however, a bituminous coal be selected it is necessary to introduce "scrubbers," etc., to thoroughly remove the dirt and tarry vapors. To obviate this necessity, coke and anthracite are much used in the smaller generators. The following are analyses of producer gases:

	From Anthracite.	From Bituminous Coal.	From Coke.	From Wood.
	p.c.	p.c.	p.c.	p.c.
Hydrogen	20.	10.	10.	20.97
Methane	....	3.	....	2.61
Ethylene	....	0 5	....	.28
Carbon monoxide	25.	23.	29.	13.27
Carbon dioxide	5.	5.	4.5	15.96
Nitrogen	49.5	58.	56.0	46.80
Oxygen	0.5	0.5	0.5	0.11
Calorific value (B.T.U.)	144	144	125	140

The apparatus in general use consists of two steel cylinders lined with fire brick, connected on the top and bottom with pipes, a fan for air, a boiler and gasometer. Fuel is charged at the top; air is blown in, also at the top, and comes into contact with the fresh fuel. The product of the partial combustion thus induced is the "producer" gas. Together with any tarry distillates, the gas is drawn downwards through the deep charge of incandescent fuel and out through the bottom of the producer. It then passes through the boiler, where its high temperature is utilized to generate the steam which is used for the blast, and is farther cooled to about atmospheric temperature in its passage through the water-sprayed, coke-filled trays of the "scrubber," whence it is led to the gasometer. When by means of regulating the amount of air admitted, the fuel bed has been raised to the desired temperature, the air blasts are discontinued. The valves are now adjusted so as to throw the two generators in series—in other words, so that the current will go upwards through the first generator, and thence downward through the second. Steam is at once admitted under the grate in one generator, and on its passage through the incandescent fuel is split up at the temperature of the fire, and, its elements combining with the carbon of the fuel, forms that mixture of gases known as "water gas." It then travels across the top connecting pipe to the steam generator and down through the latter, passing out from the bottom of this generator to the boiler, to the "scrubber" and thence to the gasometer. The

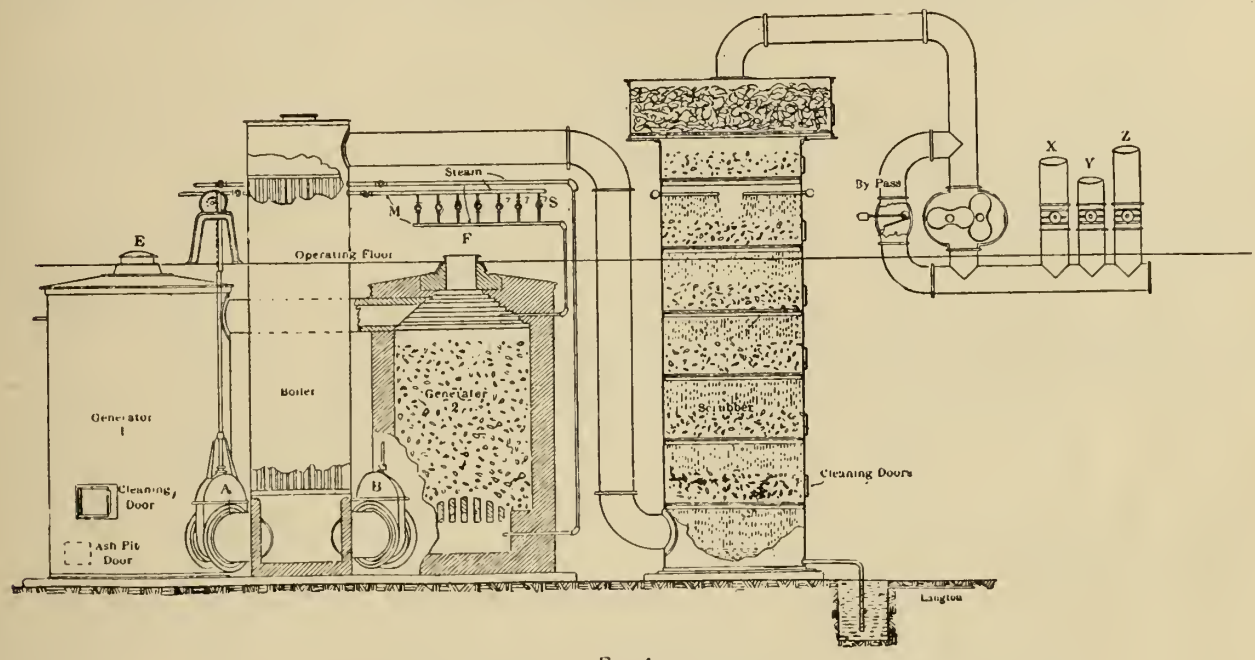

FIG. A.

* Read before the Canadian Section of the Society of Chemical Industry.

essential feature of this arrangement is that with bituminous coals, the tarry vapors liberated from the green fuel in one generator are forced through the hot fuel bed of the second, by which means they are completely gasified. The current of the steam is reversed at intervals. A good example of this type is illustrated in Figure "A"; it was erected by John Langton for the Montezuma Copper Company, Nacozari, Mexico, and has been running for five years in a very satisfactory manner, the fuel being wood.

In many of the smaller plants the fan for producing the air blast is dispensed with, and the suction induced by the piston of the gas engine is utilized for the introduction of air; no gas holder is here necessary. Generators of this type are known as "suction producers," and are very satisfactory.

When the amount of gas required exceeds that corresponding to, say, 5,000 horse-power, it is usual to instal apparatus for the recovery of the by-products. The best known system of this kind is the Mond, which has of recent years been used with great success. A 20,000 horse-power plant under continuous operation in England produced about 3,000 tons of sulphate of ammonia in a year; after deducting all expenses for operating, the profit on this amounted to nearly $1 per ton for fuel. The only Mond plant in America is at the works of the Solvay Process Company near Detroit, where a saving of fifty cents per ton of coal was effected with a daily consumption of 150 tons.

It may be asked why ordinary illuminating gas cannot be used for power purposes. The answer is that it is too dear. The explanation of the difference in price is a simple one. Disregarding minor factors, we may say that, in order to obtain a gas of sufficient illuminating power for house lighting, the distillation of coal is conducted in such a manner that only a portion of the coal is gasified. Immense quantities of coke, tar, etc., are left in the retorts and mains of gas works. In the case of producer gas, the conditions are such that the fuel may be entirely gasified. Gas producers therefore yield an immensely larger quantity of gas than ordinary gas retorts—the increase is, in fact, so very large as to make producer gas a cheap fuel, whereas coal gas is a dear one.

Progress of Modern Gas Engines

By C. Charles Maison, M.E.

Historical.

IN writing upon the subject of modern gas engines, it may be thought that a historical standpoint is out of place, but in reflecting at the progress made during the last 45 years it is remarkable how many of the improvements we are apt to regard as new are merely the embodiment of suggestions made by those engaged in bringing the gas engine into practical use to-day. Gunpowder, after its discovery, was sought after by early inventors to utilize its potential energy for their use as well as for destruction of their fellowmen. In consequence of this search many attempts were made to explode gunpowder in a cylinder as early as 1678, but owing to the mechanical difficulty to overcome in obtaining continuous and regular explosions with such a substance, its use was abolished. About the year 1792, however, Dr. Watson discovered that gas could be distilled from coal, and was experimented upon and demonstrated when again the subject of internal combustion was experimented upon. The first patent recorded, setting forth the use of explosive mixtures of coal gas and air in motors, was obtained by John Barber. He explained how a wheel, with vanes upon its circumference, may be driven by releasing the pressure of an explosion through an orifice placed in proximity to the vanes. It was just about this time the world-renowned James Watt brought about important development of the steam engine, which at that time was a source of powerful assistance in the mining industry, but the gas engine was undergoing much experiment, and another patent was obtained by Libon, setting forth the advantages of compressing the gas and air before entering the explosion cylinder. Therefore, two of the principles had been explained upon the merits of which later engines became a success.

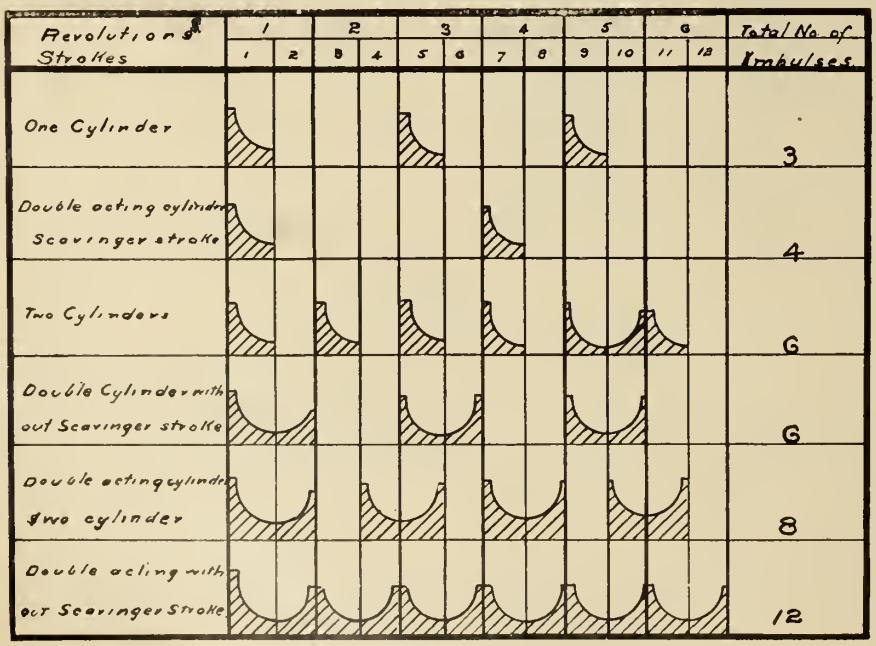

FIG 1

Action of Gas Engine.

There are numerous types of gas engines, and their comparative cycles is shown in Fig. 1, in which the shaded squares represent indicator diagrams taken from the back or front of the piston when an explosion takes place. It is seen that in a single cylinder engine, in six revolutions, only three impulses are given to the piston.

1st. Outstroke—Explosion and expansion.

2nd. Instroke—Products of combustion expelled.

3rd. Scavenger stroke, outstroke — Draws in air.

4th. Scavenger stroke, instroke — Clears cylinder.

5th. Outstroke—Draws in gas and air.

6th. Instroke—Compresses ready for explosion.

It is therefore evident that the back of the piston receives one impulse every three revolutions. Similiarly the front

of the piston receives one impulse every three revolutions, hence during the six revolutions two impulses are received by one side of the piston and two on the other.

Testing.

It is comparatively an easy task to test engines when specially fitted up for experimental work, and involves but little forethought from the experimenter. When, however, complete tests are to be made by the use of impromptu apparatus, there is ample scope for the ready exercise of one's wits in arranging simple and reliable means of measuring the quantities to be dealt with. In what follows we shall confine to gas engines, that is, not in conjunction with the machinery it may be driving. There are cases in which the work done by the driven machine is easily ascertained. For instance, the horse-power obtained from the terminals of a dynamo driven by a gas engine affords a measure of the useful work done, and, making allowance for the efficiency of the dynamo, gives the work transmitted from the engine flywheel to the dynamo pulley. But in every case the efficiency of the machine has to be allowed for, and as this

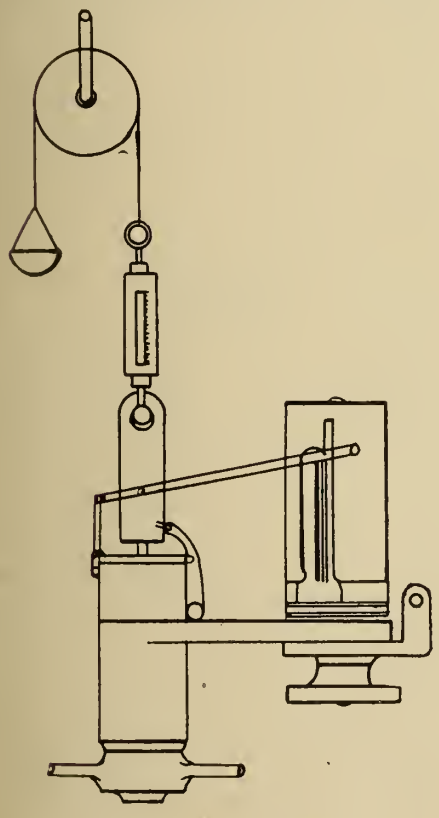

FIG 2

may be a rather uncertain quality, the only reliable method of testing is to run the engine separately, and to measure the power derived from the fly wheels by suitable means.

Indicating.

The diagrams obtained from gas engines cannot be relied upon, though they may, with careful manipulation and a suitable instrument, be considered accurate enough for practical purposes. Before any important trial is to be made the indicator springs should themselves be tested under the temperature and conditions likely to occur. The

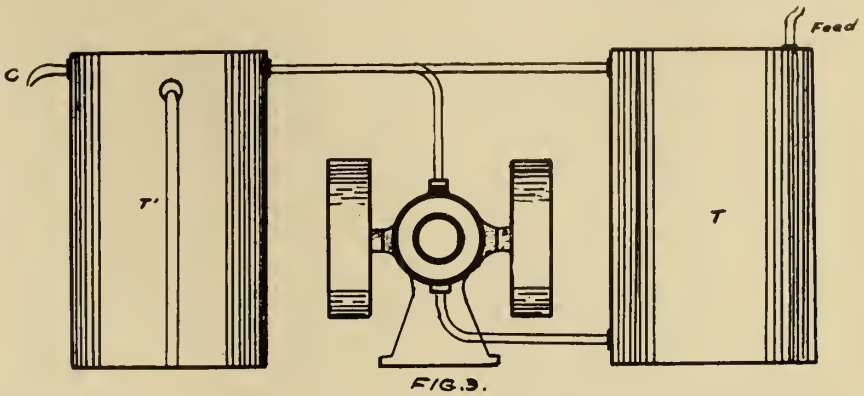

FIG. 3.

average difference in the deflections of indicator springs when hot and cold amounts to as much as 5 per cent., and more in some cases. A cold test is, therefore, no guarantee.

A simple method of testing the springs in the case of a gas engine is to construct a stirrup of brass, as shown in Fig. 2, it having a hole in it sufficiently large to allow the indicator piston rod to pass through it. This stirrup is placed in position by disconnecting the links attached to the pencil lever. Then obtain a 100-lb. spring balance, and carefully list it, with the stirrup attached against standard weights, noting the plus or minus errors, if any. Then pass the cord attached to the upper end of the balance over a suitable pulley, as shown. If a spring is being tested which is supposed to register 100 lbs. per square inch for every one inch vertical movement of the pencil on the drum, put the indicator on the engine and arrange the tackle above as shown. Start the engine, and whilst running slightly turn on the indicator cock so as to heat up the spring. When the indicator is at its working temperature close the indicator cock and mark off the atmospheric line on the drum, revolving the latter by hand. Then load the balance until it reads 10 lbs., and mark off the corresponding height of the indicator pencil. Proceed in like manner by increments of 10 lbs. at a time until the limit of the instrument is reached. Carefully measure the diameter of the indicator piston and obtain the area. For example, suppose our piston to be 0.5 square inch, and suppose when the balance reads 50 lbs. the movement of the pencil above the atmospheric line measures 1.03 in. The pressure per sq. inch at 1.03 in. rise

$$= 100 \times 1.03 \text{ lb per square inch.}$$

But the actual pressure upon an area of 0.5 square inch is 50 lbs., which is

$$\text{equivalent to } \frac{50}{0.5} = 100 \text{ lbs. per square inch.}$$

We see, therefore, that the indicator is recording a pressure 3 per cent. in excess of the real pressure acting upon the piston. When taking indicator diagrams from a gas engine it is advisable to keep the pencil upon the diagram paper for about half a minute, in order that a series of diagrams may be taken. If the engine is running at full power, the pencil will traverse the same path during each cycle and trace one distinct diagram. If, however, the engine is running lightly loaded, it is possible that it may not receive a full charge of gas, owing to the action of the governor, therefore the pencil will trace out a fresh diagram each time for each cycle.

The springs used for indicating gas engines are necessarily heavy, being

$$\text{from } \frac{1}{120} \text{ to } \frac{1}{250}.$$

Therefore only the compression, explosion and expansion curves are clearly shown upon the diagram. It is, nevertheless, important that the small variations in pressure during the exhaust and suction strokes should be ascertained as a check against bad valve setting and undue throttling in the pipes. To prevent the spring being subject to excessive compression during the explosion it is usual to pass a brass pipe $\frac{1}{2}$ inch in length over the indicator piston rod before adjusting the instrument for use. This arrangement will stop the spring from being crushed.

Special Considerations.

There are three important observations to be made with respect to the measurements of water jackets in gas engine trials :

1.—The quantity (measured in lbs.)

2.—The temperature of the inlet (measured in deg. Fahr.)

3.—The temperature of the outlet (measured in deg. Fahr.)

But the most convenient way of measuring the weight of jacket water depends so much upon local conditions

that no specific advice may be given. Fig. 3 shows such an arrangement which may be very interesting. Empty tank (T) by a syphon and plug the orifice of the upper circulating pipe leading into tank (T'). No circulation through the jacket is now possible without opening the feed cock (C). The feed water passing to tank (T') will pass through the jacket and find its way to tank (T). This tank may be calibrated to read pounds of water either by means of a float or by the insertion of a glass tube passing up the outside of the tank. The indicated horse-power of a gas engine is never a very certain quantity, yet it is calculated in trials. The inertia of the indicator levers, the effects of high temperature upon the indicator spring, and the difficulty in obtaining a true average from a number of diagrams when the engine is running below its full load, all contribute towards inaccuracy. For these reasons the ratio of a brake horse-power to indicated horse-power cannot always be relied upon as being correct, in consequence of which mechanical efficiencies of gas engines must be regarded with doubt, unless we have complete access to all the details of the test.

Figuring the Horse-Power.

The indicated horse-power, however, may be computed as follows, in which

I = the indicated horse power.

P = mean pressure per square inch upon the piston.

L = length of stroke in feet.

E = number of explosions per minute.

A = area of cylinder in square inches,

then we have $I = \frac{L E A P}{3300}$.

The most convenient way in working out a number of diagrams is to work out in decimal form the fraction $\frac{LA}{3300}$, and record this as the engine constant.

The factor we require to determine from the diagram is the mean pressure per square inch. Vertical measurements give pressures, and horizontal measurements distances, therefore the length of an ordinate measured with the scale of pressures gives the pressure per square inch at a particular point of the stroke. But if the pressure remained constant throughout the whole stroke, the diagram would become a rectangle, and the product of pressure and distance would give the work done. From this we prove that the length x breadth, or area of the diagram, represents to a scale the work done per stroke. The mean pressure, therefore, upon the piston may be found either by getting the average height of a set of equidistant ordinates, or by dividing the area of the diagram by the length, using instruments known as averagers. But to facilitate time, and most expeditious way, divide the diagram into ten equal vertical parts. Sub-divide each of these by a dotted line passing through their centres. It is required to find the height of these dotted lines. Take a strip of paper and mark off upon its edge the length of the first ordinate, then add to this the length of the second by applying the paper to the second ordinate. In this way the sum of the lengths of the ordinates may be obtained. Measure this with a rule. Suppose this gives us 5.08 in., we know that the average height will be 0.508 in.; but if the diagram is taken with a 100 spring, our mean pressure becomes 50.8 lb. per sq. in. Considering the difference between the gas and steam engine it is important that calculations should be dealt with independently.

The mechanical efficiency of a gas engine may reasonably be supposed to reach 80 per cent. This rating, however, is sometimes exceeded, in consequence of which it is better to underestimate, as no engine will develop its highest efficiency unless it is adjusted to perfection, and in the exigencies of modern practice this should not be relied on. But assuming 80 per cent. mechanical efficiency, we shall require a cylinder capable of developing $\frac{20}{0.8} = 25$ indicated horse-power.

Comparative Efficiencies.

While in steam engines the subject for consideration would be the maximum boiler pressure at our disposal, the very high thermal efficiency of the high-power gas engine and its practical application to supplying power in iron and steel plants have made it a strong competitor of the reciprocating steam engine, and have created a demand for this type of prime mover. To begin with, the efficiency of the gas engine exceeds that of the steam engine of either the single noncondensing, compound condensing or multiple cylinder types. In many cases the efficiency of gas engines has been based on indicated power developed in the working cylinders without deduction covering the power absorbed within the engine itself. Such quoted efficiencies are misleading, and without question the correct figures should be upon the effective brake horse-power. They should show the difference between the amount of heat actually consumed to deliver a given horse-power upon the crank shaft, as compared with the amount of heat which is theoretically equivalent to this same amount of power.

Assuming the thermal efficiency to equal 8,000 B.T.U. per brake horse-power where coal is used as a fuel, the consumption per effective horse-power would be for the same grade of fuel in direct proportion to heat consumption of the plant, and coal having a heat value of 13,500 B.T.U. per pound, the coal consumption for a plant operating say 3,000 hours per year, with 10 per cent. added to this for banking, would be over 11,000 pounds of coal per brake horse-power per year, with a steam engine plant having in use a simple noncondensing engine. There would be a consumption of 6,400 uounds of coal per brake horse-power per year with a steam engine plant using compound condensing engines, while with a gas engine plant where the gas is generated by a producer plant, the consumption would be 3,500 pounds of coal per brake horse-power per year, and this would be 75 per cent. saved by using a gas engine instead of using a simple non-condensing engine, and a gain of nearly 52 per cent. by using a gas engine instead of the compound condensing steam engine, there being a saving of 3,350 pounds per brake horse-power per year in the last named case, and 8,200 pounds per brake horse-power per year in the former case. Gas engines in general have passed the experimental stages, and rapid advancement of its use universally, both in plants, ships, and any place where power is required, and to effect a saving, even though the cost of a gas engine plant is greater than for steam engines of the same power.

UNITED STATES STEEL AND CANADA.

Despatches from New York and other places have been seen in Montreal which testify to the fact that some effort has been made—is being made—to sell the control of the Dominion Steel Co. to the United States Steel Corporation. Perhaps a confirmation of this may be forthcoming after the meeting of the directors of the American company, which was held in New York on April 24. Just prior to the annual meeting of the big American concern, which was held in Hoboken, N.J., on April 16, and just after it, too, there were meetings held in New York by interested parties, and that James J. Hill is no stranger to these negotiations is well known on the "inside." Then the fact stands out that the promoters of the sale are already in control of about 100,000 shares of the Dominion Steel common, and the addition of another 25,000 shares will make the deal feasible either as a merger or as a control. It is said by knowing ones in Montreal that this quantity of shares will be available in the open market when the time is ripe for the New York magnates to say the word "proceed."

Mechanical Reviews

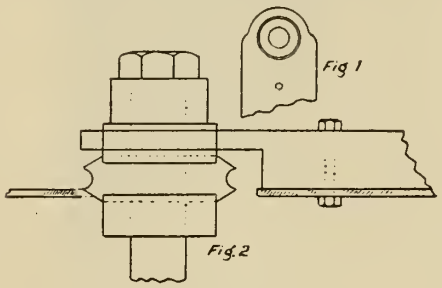
OPINIONS AND STUDIES WORTH NOTING

CARING FOR GASOLINE ENGINES.

COMPLAINTS regarding gasoline engines giving trouble are not always due to defects in the engines. In fact, we have found that 95 per cent. of such complaints were occasioned by the carelessness of the person in charge of the engine. We often receive letters saying that "My engine ran well and gave me no trouble for a year or two; but now I cannot get it to run." Usually we find in such cases that the appearance or condition of the engine indicates neglect and the only wonder is that the engine kept up so long. The great majority of persons who have trouble with the gasoline engine would have trouble in operating any kind of machine. They look upon anything that the engine might naturally require of them as trouble. Keeping the engine clean, oiling the engine, starting the engine, keeping it properly supplied with water, adjusting nuts and bearings when they need it, all are considered trouble and consequently are not done properly.

Contrast this class of operators with many from whom a complaint is never heard and you will find that the later makes it a pleasure and takes pride in doing the very things that the former regards as trouble. There never seems to be any trouble with his engine. Everything is trim and neat about his engine and engine room, and it always starts well and runs until he is through with it. The verdict of his less careful neighbor is that he has a much better engine than his own, which doesn't need his constant attention. The engines may be built just alike, even by the same manufacturer. The careless operator concludes that he has the worst one ever built, while his neighbor must have succeeded in getting the "best ever." If any difference, the careless operator may originally have had the best engine, but after a year's use it is no match for his neighbor's. His constantly grew worse during the year's use, while the engine of his neighbor apparently grew better. There may have been practically no difference originally in the construction and running quality of the two engines. But there is a wide difference in the management and care given the engines by the owners. The appearance of the engines indicates it. The one is literally covered with grease and dirt, is loose in its adjustments and runs with a wild and deafening clatter. While the other is "clean as a pin," even the roof under which it is located is clean and in order, all the adjustments are as they should be and the engine runs quietly and with such energy as to indicate that it is developing all the power it is rated.

Let us consider some of these details, which require from five to thirty minutes of someone's time every day before starting the engine. If the foundation bolts or nuts have worked loose it is necessary to take enough time to tighten them so that they serve their purpose. If an engine has a foundation at all it is well to keep it firmly secured, otherwise it will damage both foundation and itself. A good solid foundation, one on which the engine can be held firm at all times, is the only one to consider for a stationary engine. When an engine is running the nuts that hold the moving parts in position, such as the crank shaft, connecting rod, piston, valve lever, governors, spark mechanism, cam shafts, etc., will occasionally get loose and need tightening rod, piston, valve lever, governors, one's best judgment in adjusting these nuts. Take for instance the adjusting of the wrist boxes where the connecting rod joins on to the crank shaft. If the nuts holding these boxes are drawn the least bit too tight damage will quickly result, and if they are too loose bad results will follow. There is a happy medium which every gasoline engine owner and operator should acquaint himself with very soon after he takes charge of an engine.—The Blacksmith and Wheelwright.



SHAPING MACHINE DEVICE.

DEVICE FOR SHAPING MACHINE.

I GIVE herewith a sketch that is a convincing argument to any shaper hand that work can be done and yet avoid scratching from the shaper collars. I have used this for some time. Finished work fresh from the cabinetmakers can be shaped without any trouble. Our factory turns out a great deal of work on which it can be used, and all furniture factories have more or less of it. It is especially fine for swell drawer fronts, where a bead is shaped on the lower edge, or any work that is glued first and shaped afterwards to give the same margin.

Fig. 1 represents the ground plan. It is only a small board 20 inches long, 4 1-2 inches wide, and 1 1-4 inches thick. To begin with, take compasses and make a circle 1-8 inch longer than collars to be used. Then reset compasses to make another circle 5-16 inch longer than the first one, using, of course, the same centre. Then bandsaw outside circle half way and jig out inside circle, which must be done with care so as to have the same 5-16 inch margin at front, as shown in this figure.

Now we turn to Fig. 2, showing it set up ready for operation, bolted and clamped to the shaper bed. It is much better to bore a small hole, about half way back, using a small bolt and a thumbscrew at the end that will hold it firmly to the shaper top. Place cutters so as to set in, say, "just a hair," so that the points will just clear and make a perfect bead without leaving any flat place at top of shaping. Raise or lower the spindle as the situation may demand, so the bottom points of cutters will be in line with shaper tables.

These sketches will, I think, clearly illustrate what I have endeavored to explained.—C. O. P. in Wood-Worker.

SOME POINTS ON THE CARE OF AN ENGINE.

A STORY going the rounds of the daily newspapers tells of a number of mining promoters who were traveling through Mexico and at one of the stations one of the travelers got off the train and stood watching a Mexican mechanic who was going from car to car, "sounding" the wheels, presumably to test their condition. He was a fair type of a native "skilled workman." Just to draw him out a little, the American inquired of him why he tapped the wheels.

Setting down his torch, the man, staring in amazement, said: "Because the master mechanic tells me to."

"What good does it do?"

"I do not know, senor," said he. "The master mechanic tells me to strike each wheel, and I do so. That is enough for me."

"How long have you been working at this job?"

"Two years," he replied.

For two years he had been going through the form of sounding the car wheels, without the slightest knowledge of the object of the test or the slightest curiosity concerning it!

Had the story been told of a Yankee mechanic we might have thought that the mechanic was playing a trick on his interrogator, but, assuming that the Mexican was mentally of the capacity intimated, this story indicates an enormous lack of interest in his work.

Falls on Metapedia River, Quebec.

It is not unusual to find just such cases among operators of gas engines. If one happens to be around when a gas engine is being started by one of this class of help, he will often find that the engine fails to start. On trying again, or perhaps on several occasions, the engine will start, and, to the man who is at all of an inquiring mind, the question at once arises: "Why didn't the engine start the first time?" Perhaps the onlooker will make this inquiry of the engine operator, and many and many a time when I have done so, have I been answered, "Oh, I don't know. You can't ever tell what a gas engine is going to do."

Last Summer a party of pleasure hunters started out in a small motor boat for a trip. After being out a short time something happened to the engine, but they finally succeeded in making a landing and called on a man who was a gas engine expert to help them out. The host of the party was greatly embarrassed at the failure of his engine and offered to pay quite a liberal sum if the expert could get the engine fixed up quickly. After looking the engine over a short time he found the trouble was easily remedied. Here is what he told me of it:

"The old man was getting a little anxious and asked me if I thought I could fix it up. I told him I had never yet failed to get an engine going and I guessed I could get this one to run. 'I'll give you $5 if you get it to go in an hour,' said he. Well, I looked the engine over a little and finally I found the trouble was that a valve in the gasoline supply pipe had evidently gotten accidentally partially closed by some one brushing against it, and, of course, the engine did not get any fuel, or very little. When I showed them what the trouble was you can imagine their chagrin that they couldn't find it."

Now, the man who had that engine in charge had a mind much like the Mexican mechanic, unless he had just purchased the engine and it was new to him.

In another case a man spent a long time trying to start his engine and finally sent for an expert who found that his sole trouble was he had failed to throw in his battery switch and was therefore getting no spark.

Here is another incident which recently came to the writer's attention. A 45-H.P. gas engine was installed in a shoe factory and had been in use some time when the firm secured a man as an all-round machinist to take care of the shoe machinery, etc. Not long after he came he discovered that the gasket on the cylinder head was leaking and allowing water to get into the cylinder. He took off the head, and, on removing the gasket, found quite a number of gouges in the face of the cylinder. They looked to be marks of a cold chisel, and on making inquiry he discovered that the "shoemakers" formerly having the engine in charge had been in the habit of removing the asbestos gasket with the assistance of a chisel. They had not thought that it would make any difference in the head whether there were a few gouges in it or not, and the result was that it was only with difficulty that even the machinist could keep the joint water tight. To add to his difficulty, a water tank was placed on the second floor and the water from the jacket connected up to this tank. The pressure of the tank full of water at considerable height above the engine cylinder of course tended to increase the trouble.—The Gas Engine.

NEW FORGE-SHOP EQUIPMENTS.

Numerous large manufacturing establishments are awarding contracts for new forgeshop equipments to be installed during the Summer and similar equipments for manual training schools will be placed in many institutions during the vacation season. Many of the contracts are being obtained by the Buffalo Forge Co., which is at present busily engaged in manufacturing forge-shop equipments. Recent large orders obtained by the Buffalo Forge Co. have come from the Midvale Steel Co., of Pennsylvania, and from the Lynn works of the General Electric Co. Orders are also on file for the Calumet (Mich.) High and Manual Training School, and the Indiana Reformatory at Jeffersonville.

Practical Questions and Answers

Sparking of Electric Machines.

Ques.—What causes sparking at the brushes of an electric dynamo or motor ?

Ans.—If the dynamo or motor is running under constant load the only reasons there can be for sparking are :

(1) The brushes may not be set at the neutral points. If this is the only fault it can be remedied by moving the brushes while the machine is in motion until sparking ceases.

(2) The tension on the brushes may be too little or too great. In case it is too little the brushes will chatter and jump up from the commutator, and if there is too much tension fine particles of carbon will be worn off the brushes and will short circuit the commutator bars, causing sometimes a continuous line of sparks around the commutator.

(3) The commutator may be rough and in this case the commutator should be sand-papered while in motion, the brushes being lifted during the process.

(4) The brushes may be rough, and in this case the brushes should be sand-papered. This is done by inserting the paper between the brush and commutator, thus making the brush conform to the curve of the commutator.

(5) The commutator may be dirty, and in this case should be cleaned with rag or waste damped with a light oil.

Should the load upon the dynamo be varying, or should the load or speed of the motor be changing, sparking may result from improper design. For instance if in the dynamo the load be varied, the armature reaction will vary, and if the iron in the fields is not fairly well saturated, the resultant field will be greatly distorted, thus necessitating, for non-sparking, a change in the position of the brushes, so that they may be over the neutral points, for each change in load. In varying the field current of the motor to any great extent, as is done to secure large speed variation, the position of the resultant field is sure to be altered, causing sparking at the brushes. This fact has led to the originating of the interpole motor where very great speed variations are required in the motor itself. The interpoles counteract the action of the armature current upon the field.

* * *

Proportions of Shaft Couplings.

Ques.—Are there any definite formulae for the design of ordinary shaft pulley couplings ? If so, kindly give same. Or are there any standard dimensions for same ? If there are, kindly give a list of them.

J.W.R., Montreal.

Ans.—If by "shaft pulley couplings" J. W. R. means friction clutches for pulleys, then there are no definite formulae for their design, nor are there any standard proportions for them, except in so far as individual manufacturers may have developed them. The designs of pulley clutches are very varied, a great many of them being patented. However, if he means ordinary shaft couplings, the following may be of some use to him :

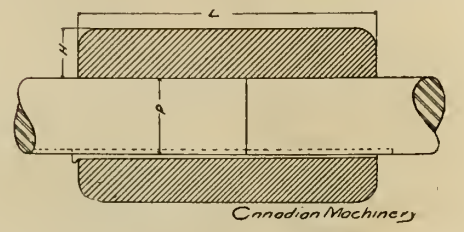


FIG. 1.—Muff or Box Coupling.

There are two distinct classes of shaft couplings, permanent couplings and disengaging couplings or clutches ; but it is probable that J. W. R. means permanent couplinas. Of permanent couplings there are several classes, depending upon the position of the shafts to be coupled together and upon the size of the shaft and the work to be done. Figures I and II are representative of the two nent couplings. Of permanent couplings for shafts in a straight line. Figure I is representative of the muff coupling, and Figure II of the flange coupling. The majority of the dimensions in each are purely emperical representing the best practice, while some are worked out from the amount of power transmitted.

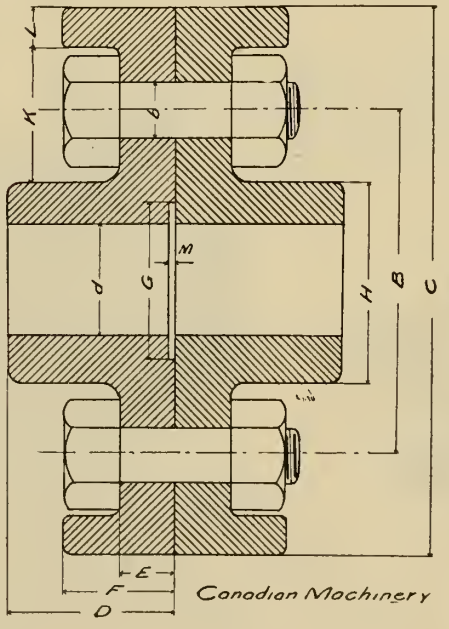

FIG. 2.—Flange Coupling.

Consider Fig. 1.

$L = 3\,d + 1\frac{1}{2}$,

$H = 0.45\,d + 0.225$.

The key is designed according to the size of the shaft.

Width of key —$b = 0.21\,d + 0.04$.

Mean thickness—$t = 0.12\,d + 0.04$.

Taper— 1 in 64 to 1 in 100.

Consider Fig. II.

N = No. of bolts = nearest whole number to $0.5\,d + 3$.

$H = 1.8\,d$.

$C = 3.4\,d + 1\frac{1}{2}$.

$D = 1.5\,d$.

$E = 0.25\,d + \frac{1}{4}$.

$F = 0.5\,d + \frac{1}{4}$.

$G = 1.4\,d$.

$B = 2.6\,d + \frac{1}{2}$.

$K = 0.7\,d + \frac{1}{2}$.

$L = 0.1\,d + \frac{1}{4}$.

M = 1/16 ins. for shafts of 1 in. diam. and less, and slightly more for larger shafts.

The diameter of the bolts used depends upon the power transmitted and upon the number of bolts.

Let b = diam. of bolt,

$T = \frac{\pi}{16} fsd^3$—as general formula for the stress in shaft is due to toque T. The shearing resistance of one bolt $= \frac{\pi}{4} b^2 fs$.

$\therefore$ " " in " n " bolts $= n \frac{\pi}{4} b^2\,fs$.

$$\text{Moment produced} = \frac{n \pi b^2 fs}{4} \times \frac{B}{2}$$

$$\therefore T = \frac{\pi}{16} fsd^3 = \frac{n \pi b^2 fs}{4} \times \frac{B}{2}$$

$$\therefore b^2 = \frac{d^3}{2 n B}$$

$$\therefore \text{and } b = \sqrt{\frac{d^3}{2 n B}}$$

But let $B = 2.8\,d$ (instead of $2.6d + \frac{1}{2}$)

$$\therefore b = \sqrt{\frac{d^3}{5.6\,nd}} = \sqrt{\frac{d^2}{5.6n}}$$

$$b = \frac{0.42\,d}{\sqrt{n}}$$

This gives the diameter of the bolts in terms of the number. In practice the diam. is increased slightly as :

$$b = \frac{0.42\,d}{\sqrt{n}} + 0.3$$

" n " is known and thus " b " is determined.

Each part of the coupling is keyed to its shaft, the dimensions of the keys being as given for Fig. I.

Metal Working **Special Apparatus** **Wood Working**

COMBINED DRILL, CUTTER AND REAMER GRINDER.

A NEW grinder has just been placed on the market by Wilmarth & Morman Co., Grand Rapids, Mich., embodying new features, its use in grinding cutters and reamers being explained by the illustrations given.

The drill grinding features of this machine are such that each drill, on account of the peculiar relation between the axis on which it oscillates and the angularity of the V shaped trough in which it runs, determines its own position by its diameter and therefore there is no necessity for other adjustment for the diameter of the drill. The grinding of a drill is therefore a very simple matter and there is no temptation left for grinding drills by hand.

The cutter and reamer grinder is simple in construction, but as shown in the illustrations, is thoroughly practical for quite a variety of shapes and sizes. The larger straight and spiral milling cutters and shell reamers are supported on te main bar as shown in illustration No. 2.

Small milling cutters that have a smaller bore than the diameter of this bar can be supported on an arbor between the centres, which are shown supporting the taper reamer in Fig. 5.

Bevel cutters are supported on the swivel head on the carriage and this is adjustable to any angle. This same head is utilized for grinding the sides of side or face mills, as shown in Fig. 4.

Straight and taper reamers are ground as shown in Fig. 5, the centres being supported on the same swivel head that is used in grinding bevel or angle cutters.

The main bar on which the plain milling cutter in Fig. 2 is supported, is clamped in a bracket which supports all the cutter and reamer grinder parts and for this there are three slots provided in the base belt so that it can be adjusted to any position necessary to bring the varions cutters and reamers in the proper position in relation to the emery wheel.

The pulley on the drill grinding emery wheel spindle is 4 3-4 inches diameter, the one of the cutter grinder wheel spindle is 1 1-2 inches diameter for 1 inch belt.

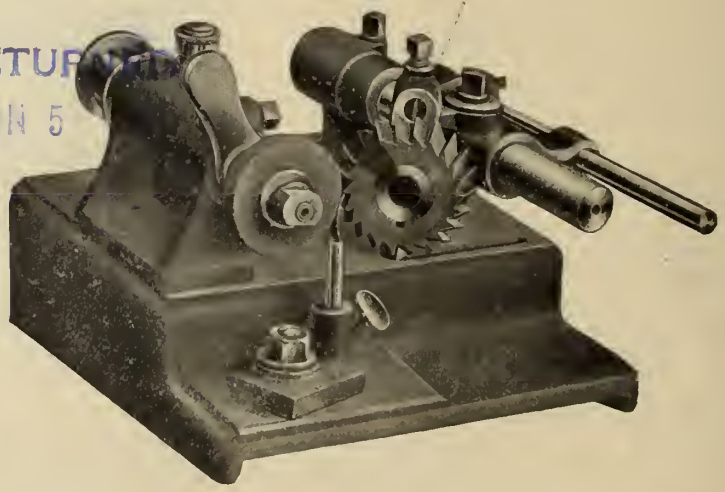

FIG. 3.—Grinding Bevel Cutter.

The cutter grinder spindle is hardened and ground and runs in an eccentric sleeve which is revolved by the handle shown to adjust the emery wheel to the cutter to be ground, this wheel being 2 1-2 inches diameter and 1-2 inch face.

"One point which this old, grey world has as yet failed to learn is that truth is infinitely better than falsehood."

SOME NEW TOOLS.

ILLUSTRATED herewith are three new lines brought out by L. S. Starrett Co., of Athol, Mass. The centre punch, for which a patent has been applied, is provided with knurled adjustable screw cap, which, working in connection with a spring, regulates the stroke. For work requiring a heavy mark, turn cap down; for work requiring a light mark, turn it up. To use it no hammer is needed. The punch being placed in an upright position over the working line, a downward pressure releases the striking block and makes the impression without danger of slipping, as is liable when a hammer is used. When adjusted for either a light or heavy stroke all indentations are of uniform size for starting the drill, etc., and accurate and quicker work can be done. The working parts are hardened, durable and accessible for such repairs as may ever be needed. The adjustable cap fits the hand, with no stroke adjusting screw through and above it to bother. The point can be ground without removing it. This punch, while small and light, is capable of giving a powerful stroke, thus taking the place of a heavier as well as a lighter punch. It is 1-2 inch in diameter. 5 inches long when adjusted for medium stroke and weighs but 3 ounces.

The draftsman's nickel-plated tea square is very light and accurate, the 18-inch weighing but 6 ounces. The head is struck up from sheet metal, the face of which is ground straight. The blade is spring tempered, .045 inches thick, 7-8 inch wide, and is riveted on top of the head so that the blade forms a bearing to guide a triangle, etc., back past the face of the head, not striking against it as would be the case if the blde was sunk into the head.

The blacksmiths' hook and handle rule is made from hard rolled sheet brass 1-10 inch thick, one 1-16 inch wide, with heavy graduations and figures, graduated from the end in 16ths of an inch on one side and from the inside of the hook in 16ths of an inch on the other, adapting them for taking correct measurements from either the outside edge of a hot piece of iron, or from the inside when held against a corner. They are graduated 12 inches, have flat handles and measure over all 16 3-4 inches.

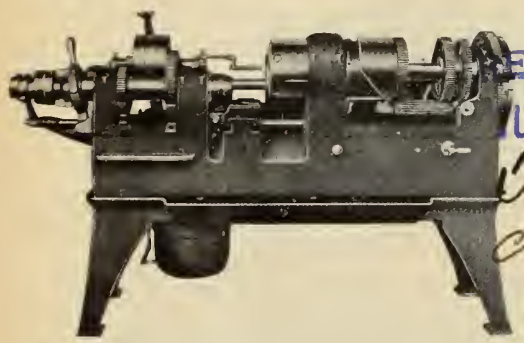
Fig.—5. Grinding Taper Reamer.

The rapid and independent adjustment of the feed of the tools is a very important feature. The operation is so simple that the feed of each tool may be changed without stopping the machine. In all other machines of this class, a change of speed—for the feed of the tools—is obtained in one of two ways: either by increasing or diminishing the speed of the feeding mechanism, and thus making a uniform change in the feed of all the tools in the series — the result in such ease is that but one tool has a proper feed; or the very expensive method of substituting cams for each movement. In our machines the feed of each tool can be adjusted independently and instantly, without removing any cams. This enables the operator to get the full cutting power of each tool. He can also change the work in a remarkably short time.

On all machines excepting those designed for light forming and brass work,

which are direct driven, we have no belt pulling on the spindle, but drive it by gears arranged on a shaft parallel to and behind it, so that a single belt running continuously in one direction will, when shifted from one pulley to the other, drive it alternately in opposite directions as is required in threading a screw and backing off the die. These gears may be, and usually are, so proportioned that the speed of the spindle is greater when running in one direction than the other. The advantage of this is made apparent when threading a long screw, as the die may be run off the screw at a much higher speed than is used in cutting the thread. Other operations and cutting off may also be run at the higher speed. By driving the spindle in this way we avoid the excessive wear caused by the pull of the belt, which has been found to be a source of serious trouble when the spindle is not so driven. The wear of the spindle being reduced to a minimum, the alignment of it with the tools is preserved indefinitely, which is a very valuable feature.



Cleveland Automatic Screw Machine.

The turret for carrying the tools is mounted on a shaft having an horizontal axis parallel with the spindle. The tools are inserted in the end. It is locked and indexed at its periphery, and as the tools are inserted in concentric order, and in a circle considerably smaller than that in which the locking is effected, they are held very rigidly in line with their work. The movement for reversing the spindle when threading or tapping is practically instantaneous. The full power of the belt is retained until the die or tap has finished its work. The cross-slide carries two tool posts, one or both of which may be used, as the operations may require. The tool posts on all machines are constructed for the use of circular forming and cutting off tools. When the character of the work requires, tool posts will be constructed for the use of flat tools. Circular tools can be ground on the cutting face without changing their form, and will therefore produce work of uniform shape until completely worn out. Convenient means are provided for the adjustment of tools.

quote:

EMERY GRINDER

A TYPE of emery grinder calculated to supply the need of the practical machinist is shown, being the product of the plant of D. McKenzie & Co., London. It is very heavy and stands 40¼ inches from the floor to centre of spindle. The bearings are 6 inches long, having a 1¼ inch mandrel. The rests swing on a round shaft. A special feature of the rest table is that it can be swung at any angle or can be used as a disc grinder for flat surfaces of planer knives, etc.

AN ANCIENT ENGINEERING FEAT.

DR. BERTHOLDT, of the University of Basle, has identified an ancient masterpiece of engineering in a tunnel built 2,500 years ago to bring spring water to a reservoir outside the gates of Jerusalem. The construction of this tunnel rivals that of the famous Simplon.

The tunnel leads into the pool of Siloam and is 360 yards long. Work was carried on from both ends, as is proven by an inscription in the tunnel and by marks on the boring tools used, showing the direction of the excavation.

What instruments were used 2,500 years ago for determining levels and directions, and how were errors detected ?—Modern Machinery.

SCARCITY OF ALUMINUM.

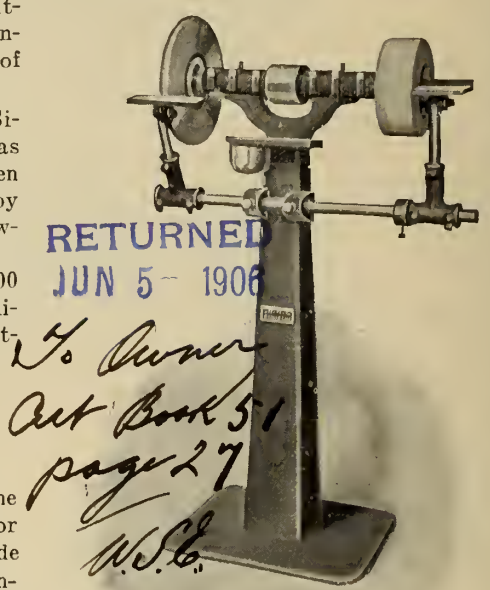
THESE are busy days in the aluminum industry, except for the manufacturers of goods made of aluminum, and if these concerns are idle or running on part time it is for the simple reason that they are unable to buy the metal at any price. The aluminum industry is growing so rapidly that the manufacturers of the article are absolutely unable to keep up with the demand. According to a New York exchange a New England manufacturer of aluminum novelties, who is entirely dependent for the progress of his business upon the supply of sheet aluminum, was unable in January to obtain promises of new stock earlier than June.

He endeavored to import the metal, but found this next to impossible, except at an almost prohibitory price. A few days ago when approached with an offer of a substantial order for novelties he was obliged to decline the order on the ground that it would be impossible to supply the goods at any stated time or at a price corresponding even approximately to his regular quotations. This manufacturer says :

"We have some foreign metal ordered conditionally for immediate use, but as we have to pay about 18 cents a pound more for it than for the local product we are not using any more of it than we are obliged to. We do not expect any aluminum from Pittsburg on our back orders before May, and we are obliged to run half time at present because we cannot get the stock."

Manufacturers of goods made of aluminum are displaying keen interest in the report that some one has discovered a new process of extracting aluminum, which will make the metal very much cheaper than formerly, and which will inject the spice of competition into the aluminum trade. It is reported that this new product is to be on the market in a few months.

The present manufacturers of aluminum are rapidly completing plans for



D. McKenzie Co. Grinder.

enormous extensions of their plants. Niagara Falls is one of the big headquarters of aluminum making in America, and the Pittsburg interests, at present predominant in the aluminum market, intend to erect at Niagara Falls the largest aluminum works in the world.

New uses for aluminum are discovered almost every day and the possibilities of the industry, if they may be judged by the progress of recent years, can hardly be calculated with any degree of accuracy. Whereas 50 years ago aluminum was known only as a curiosity found in a few laboratories, its present production in the United States alone amounts to something like 10,000,000 pounds a year. This country leads all others in its manufacture, and in the extent and variety of its uses.

BOOK REVIEWS

The Business of Contracting, by Ernest McCullough, M. West, Soc. Engineers, consulting engineers, Chicago; paper 45 pages; price, post paid, 50 cents. Chicago: Technical Book Agency.

Sound advice by a practical man is never amiss. The advice and information given in this book comes from a reliable source from a man who has had varied experience on the subject he is discussing and who is in every way qualified to speak with authority in the matter. The book itself is made up from a reprint from a series of articles in the Contractor. While in no way exhaustive it covers the ground in a fairly thorough manner. One particular virtue, and one which is too often lacking in books of this kind, is its conciseness. It discusses the staff, manager, superintendent and the foreman, in the first two chapters. Bidding on work is next dealt with in an able manner. Working methods are discussed. The book concludes with the office end of contracting and the importance of proper methods pointed out.

The Crystallization of Iron and Steel. An introduction to the study of metallography, by J. W. Mellor, D.Sc.; 144 pages; well illustrated; price, $1.60. New York: Longmans, Green & Co.

This book is a course of six lectures delivered to the engineering students of the Staffordshire County technical classes at the Newcastle High School, and summarizes the results of the more important researches made during the past ten years upon the constitution of alloys and steel. This subject is one which has only recently come into prominence and the far reaching importance of this knowledge is beginning to dawn upon the most conservative minds. The study of the subject is bringing to light the internal structure of the metals and their alloys. In the initial chapter the solidification and cooling of alloys is dealt with, after which the constituents of iron and steel are taken up. The hardening, annealing and tempering of steel is discussed in the next chapter, after which the author takes up the crystallization of iron and steel. The influence of stress and strain are demonstrated and their relation to the crystaline structure of the metal pointed out. The final chapter shows how to prepare a specimen for the microscope, as well as giving items of information regarding the instruments used. For those interested in the structure of metals and for metallurgists and students, this book is intended, and to such is a source of valuable information.

The Seven Follies of Science. A popular account of the most noted scientific impossibilities, by John Finn. 178 pages; illustrated; price, $1.25 net. New York: D. Van Nostrand Co.

Rather than a scientific dissertation, this book is a popular treatise on what is known as the seven follies of science, these being, squaring the circle, duplication of the cube, the trisection of an angle, perpetual motion, the transmutation of metals, the fixation of mercury, and the elixir of life. These are treated in an interesting manner with numerous historic references. Additional follies mentioned are, perpetual lamps, the universal solvent, palingenesy and the powder of sympathy. Following this is a small budget of paradoxes, illusions and marvels, making in all a fascinating collection of material that is of universal interest.

Extracts from Chordal's Letters, comprising selections from the series of articles entitled "Extracts from Chordal's Letters," which have appeared in the columns of the American Machinist, 11th edition, 396 pages, illustrated. New York: The Hill Publishing Co.

The style of these letters is extremely interesting and fascinating, containing as they do, much information on mechanical subjects, yet written in a manner that appeals to the reader at once. The whole trend of the letters is helpful. Methods in vogue in many places are shown up in a ridiculous light with a view no doubt to bringing about an improvement in existing conditions. While they are of prime interest to the machinist, anyone would enjoy their quaint style and quiet humor.

Gasoline Engine Ignition, by E. J. Williams; 91 pages, illustrated. Cincinnati: Gas Engine Publishing Co.

Not only is the subject matter of this book timely, but the appearance of the book when it is in a position to be appreciated should give an impetus to its sale and be the means of enlightening those interested upon a rather hidden and somewhat perplexing subject. The book is written from the author's observation in the marine gasoline engines field and being practical gives the reader pointers of no small value on the subject. The question is dealt with under the following heads: Magnetism, make and break ignition, jump spark ignition, batteries, generators, testing for trouble, kinks in power installations, horse power and wiring diagrams. The latter are of considerable value, since they show at a glance the methods of wiring of from one to four cylinders for both make and break and jump spark ignition.

Shaft Governors, by W. Trinks, M.E. and C. Housum; 97 pages, illustrated; price, 50 cents. New York: D. Van Nostrand Co.

The expression used as an introduction to the preface of this little book, "There are more forces in a shaft governor Horatio than are dreamt of in your philosophy," indicates the key note of the author's thought in dealing with the subject. Being men occupied in designing and adjusting engines and their parts, they are in a position to deal with the subject thoroughly. The matter is first dealt with from the theoretical standpoint. The centrifugal movement being calculated, as well as the mass of the valves reduced to centre of eccentric, and re-acting moment caused by friction of the valve reduced to theoretical value by formulae, the matter of friction is discussed and the different styles of governors described. A feature of this book is the neat diagrams appearing as inserts and which add a clearness to the subject matter that would not otherwise be obtainable.

The Indicator Handbook. A practical manual for engineers, by Chas. M. Pickworth, being Part I., taking up the construction and application of the indicator. Third edition, 130 pages. Manchester, Emmott & Co. Limited.

In this book engineers will find a practical treatise describing in a complete manner the indicator and its application, besides entering to some extent into the question of errors of the instrument. The reader is shown how to manipulate the instrument, so that if he be a beginner he is given an insight to make him take up the matter of indicating an engine with confidence. From the author's standing as an authority on such subjects, this book should meet with a good reception and no doubt those looking for information on the subject will seek to become conversant with its pages and diagrams.

ABOUT CATALOGUES

By mentioning Canadian Machinery to show that you are in the trade, a copy of any of these catalogues will be sent by the firm whose address is given.

Dinkey Ventilated Controllers. A bulletin issued by the Electric Controller & Supply Co., Cleveland, O., describing in detail their controllers for various purposes.

Asbestos. An extensive report made to the mines branch of the Department of the Interior, by Fritz Cirkel, M.E., on the occurrence, explorations, and uses of asbestos. The report is profusely illustrated and contains a number of maps showing the location of deposits, etc.

Punching and Shearing Machines. A catalogue issued by Henry Pels & Co., 68 Broad street, New York, describing completely their patented punching, shearing and coping machines. It is well illustrated. Size, 11 x 8 inches.

Locomotive Cranes. A bulletin issued by the Wellman-Seaver-Morgan Co., Cleveland, O., describing and illustrating locomotive cranes and accessories. The bulletin is a very handsome one, 6 x 9 inches.

Type U Controllers. A catalogue issued by the Electric Controller & Supply Co., Cleveland, O., descriptive of their special type U controller.

The Sturtevant Economizer. Catalogue No. 130, issued by the B. F. Sturtevant Co., Boston, Mass. This well illustrated catalogue of 48 pages, 6 1-2 x 9 inches, is suggestive of the rapid progress made by the Sturtevant Co. in the illustration of the economizer, an important factor in economic steam generation. It contains a detailed description of the economizer, with statements of its advantages, instructions regarding installation, operation and repairs, a discussion of mechanical draft as an adjunct to the economizer and a series of valuable tables relating to the flow of air, efficiency of fuels, etc.

Form I. Motors and Generators. A bulletin issued by the Crocker-Wheeler Co., Ampere, N.J., containing a complete description with illustrations of of this style of machine. Size, 10 x 7 1-2 inches.

Monthly Stock List. The stock list of H. W. Petrie, Toronto and Montreal, of new and second-hand engines, boilers, steam appliances and other power equipment.

Electric Galvanizing. A bulletin issued by the United States Electro-Galvanizing Co., 1-9 Park avenue, Brooklyn, N.Y., describing their patented processes of electro-galvanizing. Size, 9 x 4 inches.

Map of Cobalt. The Canadian Fairbanks Co., Montreal, have gotten up a map of the district of Cobalt, which they will mail to any reader of Canadian Machinery upon application.

Mica. A report made by Fritz Cirkel, M.E., to the mines branch of the Department of the Interior upon the occurrence, exploration and uses of mica. It is illustrated. Size, 10 x 6 1-2 inches.

Pumps. A small catalogue issued by the Smart-Turner Machine Co., Limited, Hamilton, Ont., illustrating and describing their steam and power pumps. Size, 6 x 3 1-2 inches.

Engineering Books. The May list of engineering books published by Spon & Chamberlain, 123 Liberty street, New York.

Bolt Cutters. Bulletin No. 20, issued by the National Machinery Co., Tiffin, O., illustrating and describing their multiple spindle bolt cutters. The illustrations are exceptionally good. Size, $8\frac{1}{2}$ x $10\frac{1}{2}$ inches.

Something New in Motor Drives. A leaflet, sent out by the Gisholt Machine Co., Madison, Wis., showing two new methods of attaching motors to machine tools.

Cutting Off Machines. Catalogue No. 43, issued by the Newton Machine Tool Works, Philadelphia, describing and illustrating their cold saw cutting off machines. The typographical work is excellent. Size, 6 x 9 inches.

Gas and Gasoline Engines. Catalogue issued by the Toronto Gas & Gasoline Engine Co., Limited, Dufferin street, Toronto, illustrating and describing their stationary, portable and marine engines and motor launches. Size, 9 x 6 inches.

Oil Engines. A splendidly illustrated catalogue issued by Crossley Bros., Ltd., Openshaw, Manchester, England, descriptive of their patent oil engines. A general description of the engine is given, together with full page illustrations of the many types of engines. Size, 8 1-2 x 11 inches.

National Gas Engines. A 52 page catalogue issued by the National Gas Engine Co., Ltd., Wellington Road, Ashton-Under Lyme, England, describing and illustrating their gas and oil engines. This catalogue is exceptionally well illustrated. These engines are handled in Canada by the Economic Power, Light and Heat Supply Co., Ltd., 40 York street, Toronto, and the catalogue may be obtained from them upon application. Size, 6 x 9 inches.

Gas and Oil Engines. A circular issued by Crossley Bros., Ltd., Openshaw, Manchester, Eng., giving the particulars of recent tests made upon their engines. These results are of considerable interest to those interested in the economy of gas engines. Size, 8 x 10 inches.

Suction Gas Plants. A circular illustrating and describing the Pintsch suction gas plants, which are to be manufactured in Canada by the Economic Power, Light and Heat Supply Co., 40 York street, Toronto. This circular contains letters of recommendation from some of the users of these plants.

FOND MEMORIES.

After years of honest toil and ceaseless hard work, he had risen from obscurity and poverty to public recognition and affluence. Instead of going to a modest threepenny concert as he had been wont to do, by way of experiment he attended a grand Wagner concert, one of those gorgeous feasts of music where every instrument endeavors to drown the sound made by every other.

"Ah!" said a friend next day, "how you must have enjoyed that splendid Wagner concert I saw you at last night?"

"Ah, I did that! It took me back to the days of youth," replied the old man.

"Yes," said his friend enthusiastically; "to be sure. I understand. Those lovely Summer days in the sweet fresh country, when you went courting with the lasses in the hay-scented fields and lanes?"

"No, my friend. It took me back to the days when I worked in a boiler-shop!"

"There are in business three things necessary: Knowledge, Temper and Time."—Feltham.

Power and Transmission

Steam Gas Electricity Compressed Air Water

PINTSCH SUCTION GAS PLANTS.

IN Canada the gas engine industry is now beginning to develop very quickly, especially in the producer gas line. Several years ago very little was heard in this country about the economy and other advantages of the producer gas plant for power purposes, but now much experimental work is being done upon these plants in Canada, and new firms are being started to manufacture these plants upon foreign patents, especially German and English.

The Economic Power, Light & Heat Supply Co., Toronto, are preparing to manufacture the Pintsch suction gas plants, a German type of producer gas plant, already in use all over the world.

The Pintsch Suction Gas Plant.—The Economic Power, Light and Heat Supply Co., Toronto.

This plant differs somewhat from the usual English and American suction plant, the ones with which the Canadian trade is most familiar. This plant consists of a producer, an evaporator, a seal and cleaning pot, a scrubber, a purifier and a governor. The action of this suction plant is briefly as follows: A mixture of air and steam is drawn by the suction stroke of the engine up through a bed of incandescent coal or coke in the producer, through the vaporizer, where part of the heat in the gas is utilized to vaporize water, through the water seal and cleaning pot and into the scrubber, where the gas is thoroughly cooled and partially cleaned, thence through the purifier, where all the fine dust is removed, and then through the governor to the engine.

The producer is a wrought iron cylinder, furnished with fire-brick lining and non-conducting filling. The vaporizer is separate from the producer, whereas in most plants it is situated around the top of the producer. The cleaning pot contains water and is situated directly under the scrubber. The scrubber is a wrought iron cylinder filled with coke which is sprayed with water, this spray being to cool the gas. The purifier is a vessel containing sawdust, where the gas is thoroughly purified and dried. A purifier of this kind is not used in any other gas plant. The governor is a patent arrangement for controlling the supply of gas to different sized engines drawing gas from the same plant. This also is something not contained in other gas plants. The advantage claimed for the separate vaporizer is that more heat is absorbed from the gas before it goes into the scrubber, and there is thus a saving in the amount of cooling water used in the scrubber. The supply of air is drawn from outside and is not heated before being drawn up through the producer, as is usual. In this way more oxygen per cubic foot of air is passed through the producer than if it were pre-heated. In sizes above 165 h.p. the plants are supplied with an air and steam mixture regulator. The producers are started in the usual way with a hand blower. When the engines are shut down the water seal is closed, thus holding a supply of good gas for the engine to start on when the plant is started up again. In starting the hand blower is used to force air up through the coal until sufficient steam has been generated to form the correct mixture, the generated gas being blown off until it is of standard quality, when the water seal is opened and the engines started.

Thousands of these plants, with a total capacity of 150,000 B.h.p. are now in operation. They have been built on sizes from 4 h.p. to 2,000 h.p. In the near future a plant is to be built in Canada for the manufacture of these gas plants. The Economic Power, Light & Heat Supply Co. will be able to supply engines in conjunction with

these plants, they being agents for the National Gas Engine Company, near Manchester, England. The firm will be pleased to receive any inquiries regarding these gas plants or engines.

THE CROSSLEY ENGINE AND GAS PRODUCER.

THE acknowledged method of increasing the efficiency of gas engines is to increase the compression and thus increase the ratio of expansion. The difficulty experienced in increasing the compression above the ordinary limits—about 110 pounds for ordinary coal gas and 180 pounds for producer, or blast-furnace gas—is that the higher temperatures resulting from any increase in compression are apt to cause premature explosions.

In view of this, a description of the new type of engine brought out by Crossley Bros., Openshaw, Manchester, Eng., in which the compression is carried to over 200 pounds per square inch, will be of interest. These engines which are illustrated in the three accompanying engravings, are operated upon producer gas, or coal gas, the producer-gas plant being shown in one of the illustrations. Premature ignition is prevented by drawing in a certain quantity of water during the suction stroke. One of these engines, an electric-lighting engine with extra heavy fly wheel, and engine cylinder 14 inches in diameter and 21-inch stroke, was tested recently by F. W. Burstall, professor of engineering, Birmingham University, and it gave a thermal efficiency of 37.4 per cent., the highest efficiency to his knowledge ever attained in a gas engine test. The calorific value of the coal gas used was 578 B.T.U. per cubic foot at atmospheric pressure, and 60 degrees F.; the cylinder volume was 1.872 cubic feet, the clearance volume 0.243 cubic feet, and the ratio of expansion 8.7; the maximum gauge pressure in the cylinder was 528 pounds, and the volume at the maximum temperature was 0.247 cubic feet; the average pressure during suction stroke was 12.8 pounds absolute; the compression curve was given by equation,

$$P V^{1.268} = 6,508 \text{ ft. pds.},$$

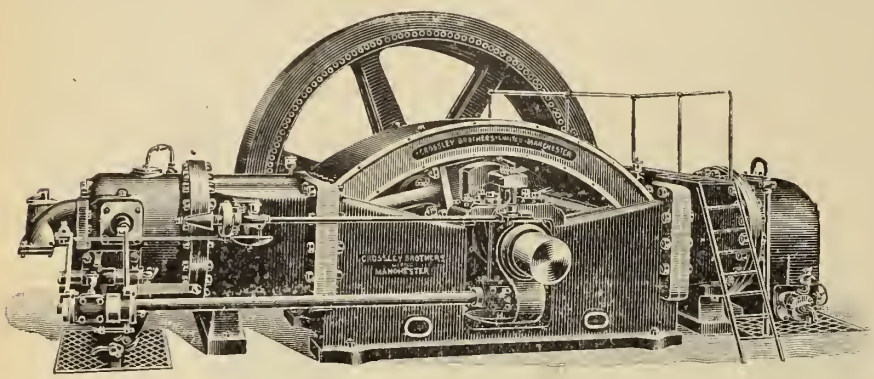
and the expansion curve by the equation,

$$P V^{1.183} = 17,610 \text{ ft. pds.}$$

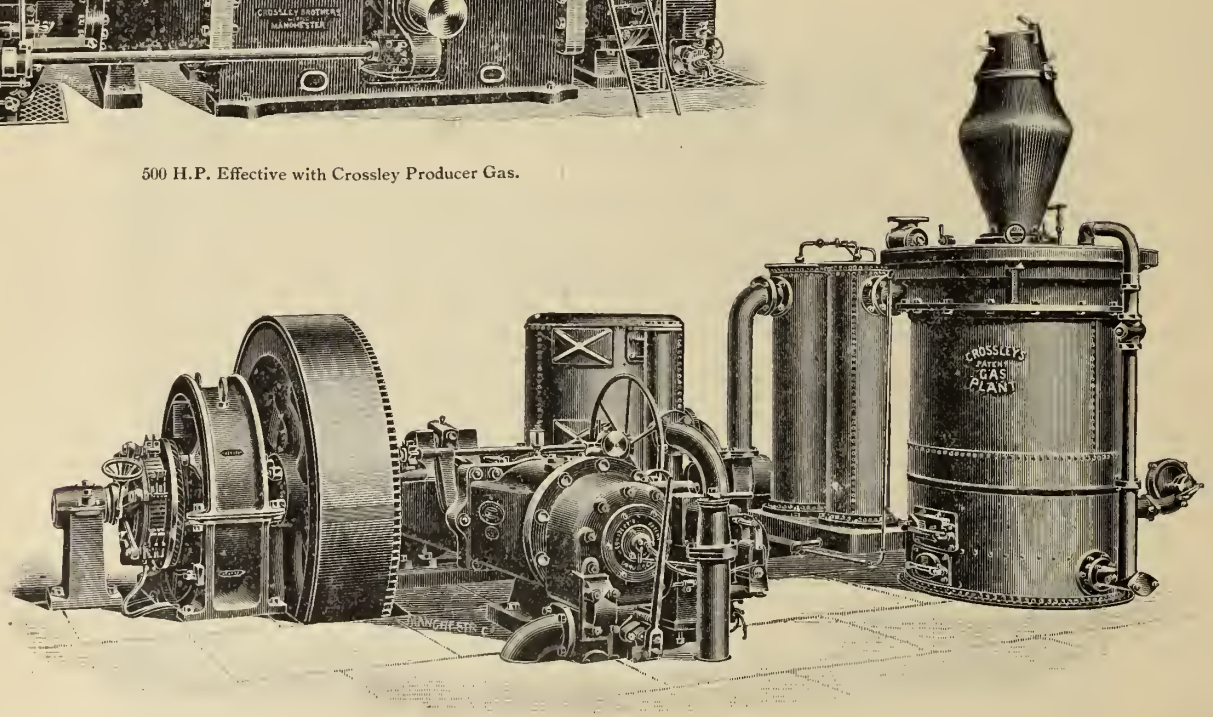
According to the report of the test, during the suction stroke the injected water appeared to turn into steam which became superheated during compression; heat passed into the charge from the walls until a pressure of about 160 pounds was reached, when there appeared to be equalization of heat; down the expansion curve the charge appeared to lose heat to the walls, at first rapidly, but towards the end the interchange was scarcely perceptible.

An important feature of the large Crossley producer-gas engines, above 500 H.P., is the equilibrium exhaust valve. One of the chief difficulties experienced in the manufacture of large gas engines is the operation of the exhaust valve. Owing to the largeness of the valve surface, the pressure upon it is very considerable; and, if the valve is operated in the usual method, i.e., by gear and worm operating the shaft keyed to the exhaust valve cam, there will be a very heavy load applied instantly to the gear and worm, having a deteriorating effect upon them. Crossley Bros. have overcome this difficulty by the use of a pilot valve close to main exhaust valve which is operated slightly before the large valve, and thus alows the gas from the compression space to press on the outside of large valve, thus making an equalized valve of it, and relieving the gear and worm of all great strain.

Crossley Bros., Limited, make both suction and pressure producer-gas plants for burning anthracite coal or coke, and they also make a plant for burning bituminous coal slack. The suction plant appears to have the greatest demand.



500 H.P. Effective with Crossley Producer Gas.



General View of Crossley Coke Gas Plant Engine and Dynamo.

TEST OF TORONTO WATERWORKS ENGINE.

VERY satisfactory indeed was the 24-hour test of the new triple expansion, three plunger steam pump at the Toronto Waterworks made recently under the supervision of Dr. Galbraith, Dean of the Faculty of Applied Science, University of Toronto. The test was arranged and conducted by Prof. R. W. Angus, B.A.Sc., assisted by the post-graduate year students.

The contractors for the pumping engine were the John Inglis Co., Ltd., Toronto, but it was built from designs made by the Allis-Chalmers Co., Milwaukee. At the test the contractors were represented by Mr. Lynch.

Results of Test.

According to the specifications the engine was to perform a duty of not less than 165,000,000 foot pounds for each 1,000 pounds of steam used. The results of the test show the engine to perform a duty well above this minimum limit. The chief results of the test are as follows:

Percentage of moisture in steam—1.22.

Average speed of plunger in feet per minute—197.90.

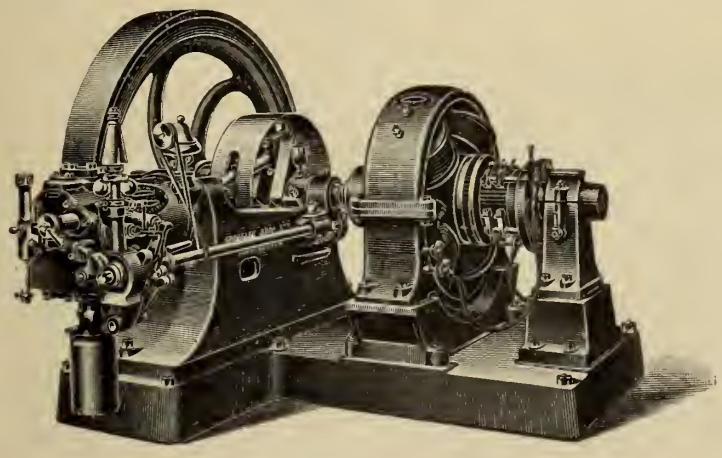
Discharge per 24 hours, Imperial gallons—15,104,031.

Duty per 1,000 pounds steam used, foot pounds—172,300,601.

A description of the manner of conducting a duty test on a large pump of this kind will probably be of interest to many readers of Canadian Machinery; but before the test is touched upon, a few facts regarding the construction of the engine must be given.

Description of Engine.

The engine is of the vertical triple expansion, condensing type, having three



8-H P. Crossley Engine and Dynamo.

cylinders and three water plungers. The steam cylinders are respectively 32-in., 60-in., and 90-in. diameter, and 60-in. stroke. Each cylinder is steam-jacketed, the high-pressure jacket receiving steam from the main steam pipe. From the jacket the steam passes in successive stages through the reheating coil in the first receiver, through the jacket on the intermediate cylinder, the reheating coil in second receiver, through a trap into the low-pressure jacket and thence to the atmosphere. Drain pipes carry off the condensed steam from the receivers and steam pipes.

The main steam pipe is eight inches in diameter, branching to the upper and lower valves on high pressure cylinder. The main exhaust pipe is 20 inches in diameter.

The clearance in the cylinders is exceptionally small, the placing of the valves close to the inner face of the cylinder heads being one means of reducing the clearance. All the valves are Corliss valves with the exception of the exhaust valves on the low-pressure cylinder, which are poppet valves; these are opened by the valve gear, and closed by gravity and compressed air.

The engine is governed by a fly-ball governor, operating upon the cut-off in the high-pressure cylinder. The cut-off for the other two cylinders is regulated with hand wheels.

Civil Book 5-1
page 28
WSL

Engine Toronto Waterworks, built by John Inglis Co., Toronto.

In starting the engine steam is admitted to the intermediate cylinder by means of a by-pass pipe from main steam pipe to the high-pressure exhaust pipe.

The pumps are single acting, and the plungers are outside packed. There are in all 1176 suction valves and the same number of discharge valves, each valve being 3 in. in diameter, and made of rubber.

The main suction pipe, 48 inches in diameter, is connected directly to the surface condenser.

The air pump, the feed pump and the compressor for compressing air to operate poppet-valves, are all attached to the low-pressure plunger.

The cranks of the engine are placed 120 degrees apart. Steam is supplied by a set of Heine boilers.

Manner of Conducting Test.

In the contract the character of the duty test was specified, and these specifications were followed. According to the specifications the engine must perform a duty of not less than 165,000,000 foot pounds per 1,000 pounds of commercially dry steam used, steam containing less than 1.5 per cent. water being recognized as commercially dry steam. In computing the duty the work done was to be computed from the plunger displacement, and from a head

representing the difference of head between a point in the discharge main beyond the last pump but inside the engine room, as shown by mercurial gauge, and a point in the supply conduit at the entrance to the pumps. In computing duty the total steam used, including that used in jackets, auxiliary pumps, etc., was to be charged to the engine. Now allowance was to be made for friction of water. The test was to be of 24 hours' duration, and the operation was to be continual against a head equal to 100 pounds pressure per square inch on the pumps. The steam pressure was to be 150 pounds per square inch.

The amount of steam chargeable to the engine was determined by weighing the condensation from the condenser, the jackets, the reheaters, drain pipes, etc. The condensation ran into tanks placed on scales.

The average diameter of the plungers was found by calipering. The stroke of the plunger was found as follows: strips of oak 1 1-2 inches square were fitted tightly between points on the frame and made parallel with the piston rods; on these were fastened brackets and adjusting screws, the axes of the latter being parallel with the strips. These screws were so placed and adjusted that the lower one just touched the bottom of a pin on the cross-head at the bottom of the stroke, and the upper one touched the top of the same pin at the top of the stroke.

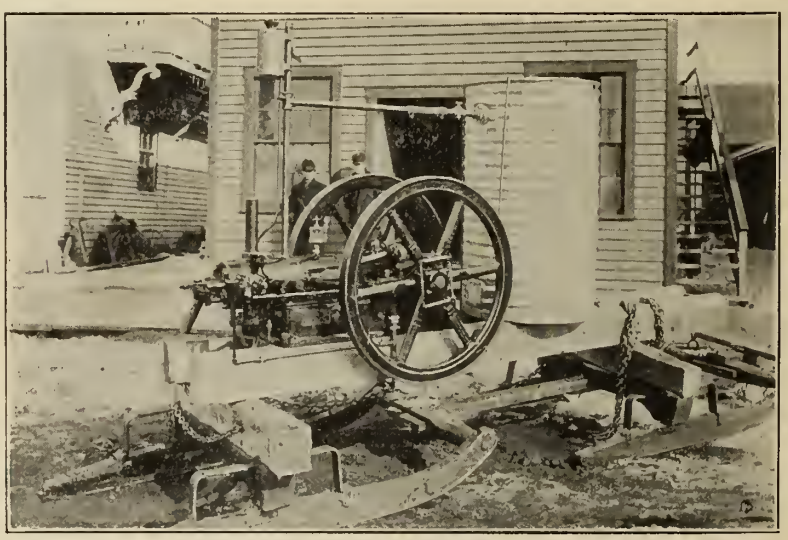
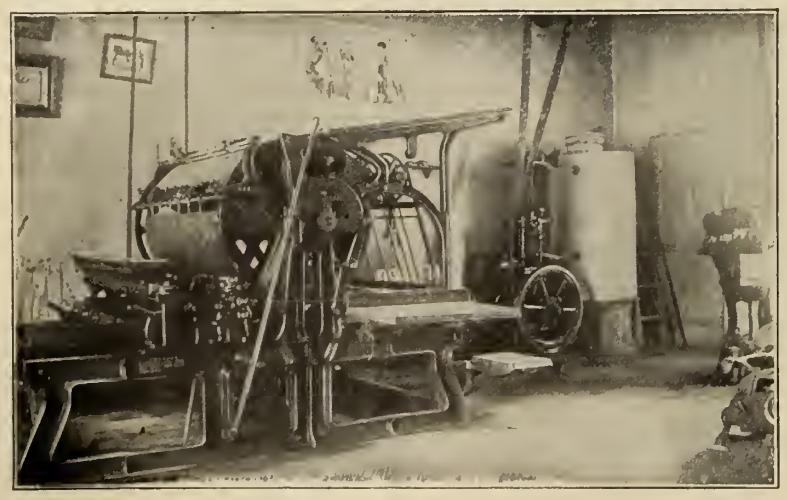
Rochester Type, McLachlan Engine.



International Engine Mounted on Runners.



International Engine Running Press.

Summary.

Observations throughout the experiment were taken at twenty minute intervals.

From the calorimeter test the quality of the steam was obtained. From the number of revolutions, as shown by the counter, the average plunger speed in feet per minute was calculated. The amount of water pumped per 24 hours depends upon the plunger displacement per revolution, and upon the number of revolutions per 24 hours; thus the diameter of the plunger being known, and the length of the stroke, the water pumped can be calculated. Since the displacement per revolution is known, and the total head, represented as a pressure in pounds per square inch, the work done per revolution can be found, and thus the work per 24 hours. The steam used in the engine is represented by the total weight of the condensation. The duty of the engine is the number of foot pounds of work done per 1,000 pounds of steam, and from the foregoing this can be found.

The discharge pressure was determined with a Bourdon gauge instead of the mercurial gauge, while the suction pressure was determined with a manometer. The discharge pressure was kept fairly constant for purposes of the experiment by throttling the discharge main, and running an auxiliary engine when necessary.

The steam pressure was determined by Bourdon gauge, protected by a water column. The pressures in the receivers were taken from gauges on the gauge board, but were corrected for the water column between the receivers and the board.

The barometer reading was obtained from the Observatory in Toronto, but was corrected for difference of level.

The speed of the engine was taken from a revolution counter.

The quality of the steam, that is, the amount of moisture, was determined by a throttling calorimeter.

The temperature of the exhaust steam was taken in the exhaust pipe, and that of the condensation in the weighing tank.

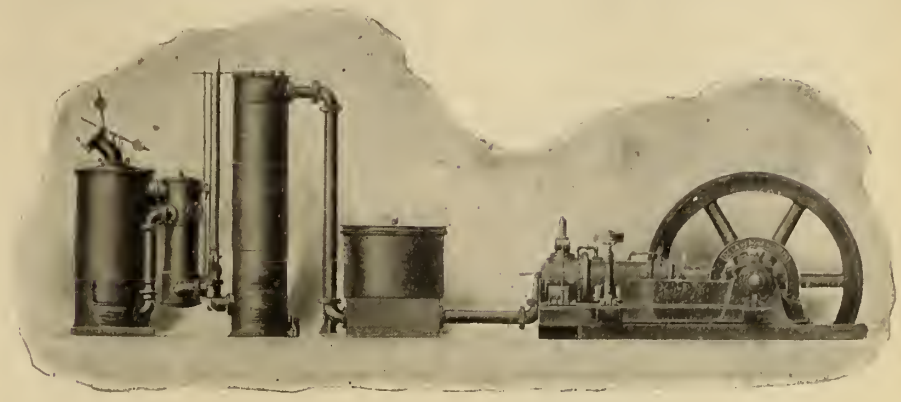
MAKING MARINE ENGINES.

THE McLachlan Gasoline Engine Co., Swansea, Toronto, who have up to the present been devoting their entire attention to gasoline traction engines and stationary engines, have now branched out into the manufacture of marine engines. The engine they are manufacturing is known as the Rochester type, shown in the accompanying engraving. These are high-speed, two cycle, three-port engines, built in units of 3 1-2 h.p. and up; they are also built with one or more cylinders.

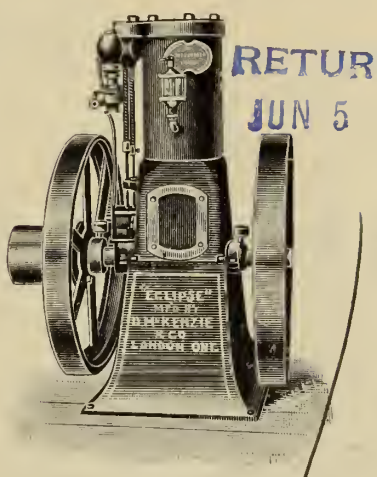
At the present time the company are putting considerable time on these engines, this being the beginning of the motor-boat season.

INTERNATIONAL GAS ENGINES.

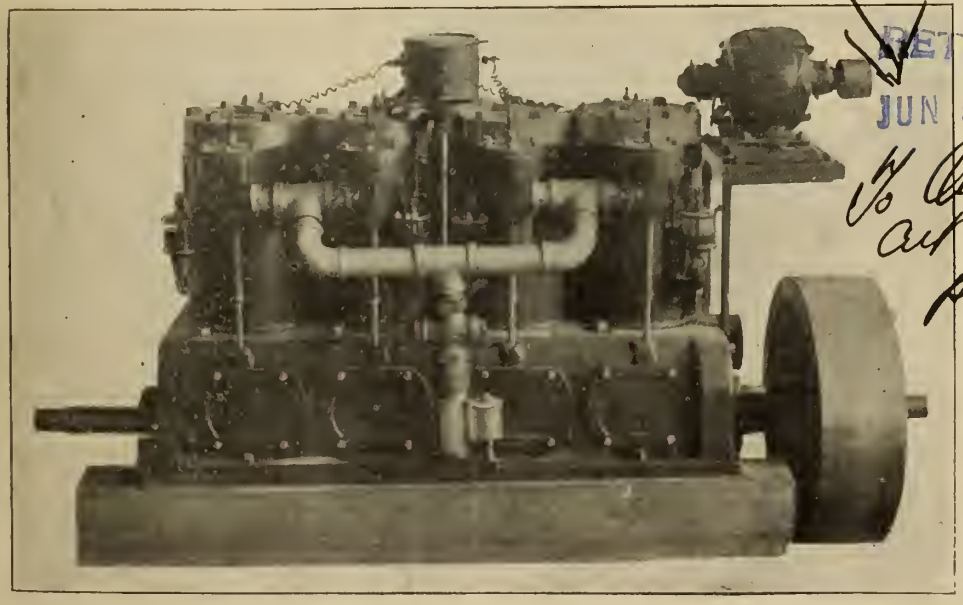
ONE of the most complete gas and gasoline engine catalogues issued is that published by the International Harvester Co. of America, Chicago. Two views of these engines are shown, one mounted on skids and the other one running a cylinder printing press. The catalogue describes in considerable detail their vertical gas and gasoline engines of 2, 3, 4, and 5 h.p., portable gasoline engines from 6 to 15 h.p., famous gasoline engines, 2 to 8 h.p., and famous pumping engines of 2 h.p., besides special attachments for these engines. Illustrations are given of various adaptations of the IHC engines, such as performing various operations around the farm, in printing offices, bakeries and plants of various kinds where a small amount of power is required. A post card addressed to the International Harvester Co. of America will bring one of these interesting catalogues, each one of which contains a large amount of information.



Koerting Suction Producer and Gas Engine.



Single Cylinder Eclipse Gasoline Engine.



D. McKenzie Co.'s Four-Cylinder Type, 40 H.P.

TWO LONDON ENGINES.

IN London, Ont., D. McKenzie & Co. manufacture two types of gasoline engines shown in illustrations; one of them is a heavy duty gasoline four-cylinder 40 h.p. engine made to meet the demand of the larger size of this type. The cylinder and cylinder caps are removable from the base, the design being such that the parts are easily accessible. The crank case is provided with large hand hole plates to get at the crank and connecting rod. Perfect lubrication at all speeds is insured by separate oil splash in the base for each throw of the crank. All valves are mechanically operated from the cam shaft.

The smaller engine shown is a 3 h.p. stationary of simple type and of easy operation, which the firm claim will operate on 1 pint of gasoline h.p. per hour.

SUCTION GAS PRODUCER.

IN the competition between steam and gas power, the suction gas producer and gas engine have become of the utmost importance on account of the fuel economy and simplicity of attendance. The advantages of the suction gas producer are well known in industrial circles, the result being a continuously increasing use of this system.

The producer gas is generated as follows: The suction of the engine draws a mixture of steam and air through the glowing fuel in the producer. The oxygen of the air forms with the carbon at the bottom part of the glowing fuel carbonic acid, which, by going upwards through the fuel, is reduced to carbon monoxide. Simultaneously the steam is decomposed into hydrogen and oxygen, the latter forming carbon monoxide by reaction with carbon. The resulting

horizontal gas and gasoline engines 4, 6, 8, 10, 12 and 15 h.p.

RETURNED JUN 5 1906

gas therefore consists mainly of carbon monoxide, nitrogen and hydrogen. The fuel to be used is anthracite, coke or charcoal. One pound of anthracite yields approximately seventy cubic feet of gas of 130 B.T.U. per cubic foot.

The principal parts of a suction gas producer plant are: (1) blower, (2) producer, (3) evaporator, (4) scrubbing apparatus, (5) pipes, valves and fittings. The blower is either a hand or a power blower, and is connected to the lowest part of the producer. The producer consists of a wrought iron shell, lined with fire bricks, and provided with ash and poke doors and a grate. The grate is kept cool by the steam of the evaporator. The producer is charged with coal through a bell hopper, which is of such size as not to require recharging of fuel too frequently. The steam and air enter the producer through a flange near the bottom and the gas leaves the producer through a flange near the top, giving off its heat to the evaporator after leaving the producer. The evaporator is a wrought iron cylinder filled with boiler tubes, which contains the water to be heated by the passing gas. The height of the water column is automatically regulated and the amount of entering air can be throttled. A three way valve is inserted between evaporator and scrubber which allows the gas to be cut off the scrubber and passed out to the flue or vice versa. The scrubber is a wrought iron tank containing water in its lower part. The upper part is filled with coke which is continuously sprayed by a rain of finely divided water. The sawdust scrubber, in which the gas is filtered, contains two or more gratings covered with shavings and sawdust.

In an engine of the four-cycle horizontal type during the first stroke the gas mixture is drawn in, during the second stroke the gas mixture is compressed, during the third stroke the gas mixture is exploded and expanded (working stroke), during the fourth stroke the burnt gas is exhausted.

The formation of the combustible mixture takes place in the mixing valve. At the suction stroke the gas and air openings of this valve always open in the same proportion. The mixture is therefore always constant and uniform, independently of speed and load. The size of the openings of the mixing valve varies according to the kind of gas to be used. Our engines have on account of this mixing valve the great advantage of easy and quick starting, and automatic and economical work.

In large engines of the Koerting type, as manufactured by De La Vergne Machine Co., New York, the combustion space gets very large as compared to the cooling area whereby the heat of compression is considerably increased, causing insufficient cooling and danger of preignition, which would interfere with the uniform running of the engine. For preventing this defect, the cooling area is increased by connecting a water-cooled projection (offset) to the cover at the back end of the valve head. Another advantage of the Koerting engines is the removable cover of the cylinder which allows inspection and cleaning of the valve head and cylinder without removing the piston.

A 75 h.p. suction gas power plant driving electric generator on a coal consumption of 1½ lbs. per k.w. hour can be seen in the shops of the De La Vergne Co.

A 60-H.P. CAMPBELL GAS PLANT.

AN illustration of an engine installed in the factory of the Simonds Canada Company, Limited, Montreal, which has been in operation for about five months is here given. This plant and engine is used for driving heavy grinding machinery used by the Simonds Company in turning out the large circular and band saws which form an important part of their product. The full load of the engine is required practically the whole of the day and is obtained at a fuel cost of nine cents per hour. In addition to furnishing gas for the engine the plant is also supplying gas for other purposes in the factory. The proprietors express themselves as pleased with the satisfactory performance of the plant. The gas plant is exceedingly simple and occupies very little floor space. The operation of cleaning and charging occupies comparatively little time. The engine is of 50 h.p. ordinary type single cylinder, and is of very massive construction throughout. The ignition is effected by an oscillating magneto of new design, which gives positive ignition at all speeds. The governing is so arranged that changes of speeds can be effected whilst the engine is at work. The governor controls automatically the supply of gas to the engine and also the quantity of gas made in the generator.

This plant was installed by Wayland, Williams & Dadson, Montreal, who have also made installations at Woodburn, Sons Co., Limited, Montreal, of a 25 h.p. engine and plant operating the factory, and also doing the electric lighting of the premises. Another installation of same size operates the factory

of the Ryall Screw & Specialty Company, Montreal, also Beauvais Frere, Laprairie.

LETSON & BURPEE ENGINES.

AMONG the newer firms in Canada is Letson & Burpee, of Vancouver, who have lately gone into the manufacture of gasoline engines. They have lately equipped a modern working plant with the best machinery on the market, and are prepared to go into the manufacture of these to considerable extent. An illustration is shown of the port side of a 3 h.p. engine. Some of the features of this engine include the cylinder and head being cast in one piece, thus avoiding any high pressure joints in the cylinder head. The water jacket covers the head as well as the wall of the cylinder and gives ample cooling surface. The cylinders are made of a grade of iron selected for the purpose and are carefully bored and reamed to size, insuring uniformity, accuracy and smoothness of bore.

In order to get proper compression of the charge in the cylinder it is important that the piston rings be right. The rings in this engine are split so that each half of the joint laps the other when compressed. They are turned after being compressed, and are crescent shaped, being thickest exactly opposite the split. This insures a perfectly fitting and evenly wearing ring.

The connecting rod is made of steel and an I cross section. Both ends are bored large and bushed with phosphur bronze, provision being made for taking up the wear on both sides.

The crankshafts are of the best machinery steel, forged from the solid bar. The crank pin and main bearings are of good length, which insures long life of the wearing parts. The crankshaft for the single cylinder engine is provided with counterweights which perfectly balance the piston and connecting rod. In the larger engines these parts balance each other. The thrust is taken by a ball thrust bearing.

NEW ONTARIO COAL.

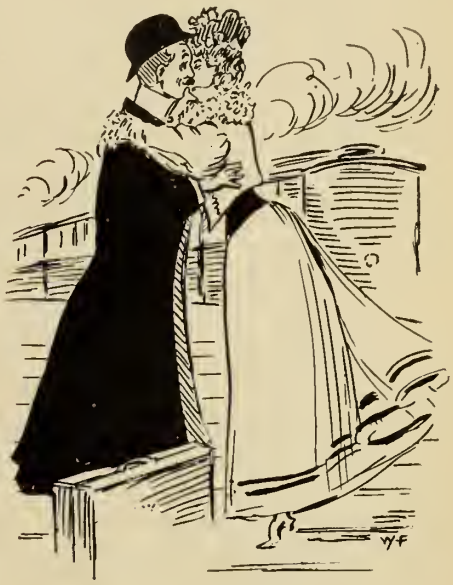
The announcement made by Hon. Frank Cochrane that anthracite coal had been found in Northern Ontario is of great importance to the province, as the industrial importance of coal to the country cannot be over-estimated. At present Canada's coal supply lies in the extreme east and the extreme west, hence the discovery of coal in Ontario, and hard coal at that, is a thing that means a lot for Central Canada. Until further evidence is produced, however, this discovery should not be too quickly taken for granted, for the same reports were circulated some few years ago, when hard coal was supposed to be found at Sudbury. A company was floated to develop these mines, but it was found that their find consisted simply of a material called anthraxolite, which is not at all valuable as a fuel.

AT THE NOON HOUR

Electrical Impulses.

Things would have been different if electricity had lighted the station, but our poet just adores gas, hence the following effusion :

I waited for the railway train,
The gas was low and dim ;
It came at last, and from the car



Electric Impulse.

There stepped a dainty dame,
And looking up and down the place,
She straight upon me came.
"Oh Jack !" she cried, "oh, dear old Jack !"
And kissed me as she spake ;
Then looked again, and frightened cried :
"Oh, what a bad mistake !"
I said, "Forgive me, maiden fair,
For I am not your Jack ;
And as regards the kiss you gave,
I'll straightway give it back."
Since that night I've often stood
Upon that platform dim,
But only once in a man's whole life
Do such things come to him.

—Electrical Magazine.

A Pi Line That Made Trouble.

The copy was illegible and the linotype man slammed in a pi line so that the proofreader would decipher the manuscript of the account of the wedding and make necessary corrections. For some reason this was not done, which is why the next day a determined looking young man with "bridegroom" stamped all over him and a tearful young woman who still had rice in her hat appeared at the office and demanded an explanation of a paragraph that read :

"Then down the aisle came the bride, who looked like ffipouxthnbgfdertyhnb."
—Ex.

Companies Incorporated

Hudson Bay Extended, Limited, share capital $50,000, to carry on mining business. The directors, J. W. McDonald, E. A. Francis and M. A. McKessock; head office, Toronto.

Camugay Tramway Co., incorporated under Dominion charter; capital stock, $200,000; to construct and maintain tramways in the City of Camugay, in the Island of Cuba; chief place of business to be Halifax.

The Laurentian Mfg. Co., Montreal; capital stock, $20,000; purpose, to manufacture and deal in woodenware. Directors are: Thomas Pearson, Geo. Pearson, W. F. Sawyer and E. P. Sawyer, all of Montreal.

The powers of the Dominion Pressed Steel Co. have been extended to manufacture and deal in all articles capable of being made from pressed steel, and to manufacture and deal in wooden handles, bales, etc.

The Cobalt Standard Mining Exchange, Limited, have been incorporated under provincial charter; share capital, $40,000. Directors, J. W. McDonald, H. L. Dunn, A. Blackman, E. Francis; head office, Town of Cobalt.

The Rapid Tool Co., Limited, $40.000 share capital, have been incorporated under provincial charter for the purpose of dealing in tools and hardware. Directors to be W. Rudins, W. Quinn and G. L. Hay, with head office at Peterboro.

The Roofers' Supply Co., Limited, incorporated under provincial charter to deal in roofers' supplies and structural material, with a share capital of $200,000. Directors, A. Dods, R. B. Rennie, G. Duthie, A. Mathews; head office, Toronto.

Coopers Ltd., Montreal; capital stock, $2,000,000; purpose, to deal in and develop mines of all kinds. Directors are: R. P. Inglis, Geo. Boulter, W. H. C. Mussen and F. H. Mackey, all of Montreal; Jas. Playfair, Midland; and Wm. Inglis, Toronto.

The Cobalt Chartered Co. have been incorporated under Ontario charter, share capital $350,000, to carry on mining and development. Directors, F. Law, A. Lebeau, E. E. Belcourt, J. N. Rattey, H. Letorneau; head office, Haileybury, Ont.

G. Duthie & Sons have been incorporated under Ontario charter with a share capital of $40,000, to carry on the business of roofers and sheet metal workers. The provisional directors are: George Duthie, John B. Duthie, R. R. Duthie, G. F. Duthie and Margaret Duthie, with head office at Toronto.

The Central Foundry has been incorporated under Ontario charter with a share capital of $200,000 for the purpose of carrying on a general foundry business. The provisional directors are H. L. Bowers, H. T. Bush and R. C. Donald, with head office at Toronto.

The Dominion Office & Store Fittings Co. has been incorporated under Ontario charter with a capital stock of $40,000 for the purpose of manufacturing office and store fittings, etc. The provisional directors are D. H. Gillies, C. R. Somerville, J. McK. McDermid, T. H. Weldon and C. W. A. Woodburne, with head office at London.

The Amalgamated Petroleum Producers Limited, have been incorporated under Ontario charter to produce and deal in petroleum and gas, with a capital stock of $40,000. The provisional directors of the company are, C. Brown, H. Quinlan, and W. M. Pontom, with head office at London, Ont.

Cobalt & Hudson Bay Developing Co. have been incorporated under provincial charter with a share capital of $100,000, to carry on the business of prospecting and developing. Provisional directors are, J. E. Day, J. M. Ferguson, E. V. O'Sullivan, A. H. Day, and J. J. O'Sullivan; head office, Haileybury.

The Bothwell Locomotive Company has been incorporated under Ontario charter with a share capital of $100,000 for the purpose of manufacturing and dealing in locomotives, etc. The provisional directors are James McLauchlan, F. W. Harrison, J. G. Hay, S. J. Parker, G. A. Bothwell and A. G. MacKay, with head offices at Owen Sound.

The National Brass Manufacturing Co. has been incorporated under Ontario charter with a share capital of $100,000 for the purpose of manufacturing and dealing in brass and other metal goods. The provisional directors are: C. D. Fergusson, Joseph Grey, and E. J. Saunders, with head office at Toronto.

Toronto & Belleville Rolling Mills have been incorporated under Dominion charter with a capital stock of $599,999, for the purpose of operating mills for the manufacture of iron and steel. The provisional directors are W. D. Morris, Henry Nicholson, G. E. Barber, R. G. Code and E. F. Burritt with head office at Belleville.

Jenkins Bros. have been incorporated under Dominion charter with a capital stock of $200,000 for the purpose of manufacturing and dealing in valves, lubricators, injectors, etc. The provisional directors are: A. B. Jenkins, F. T. Swain, E. Brady, H. D. Gordon, and W. R. Stewart, with chief place of business at Montreal.

Carbolite Carbolineum Co., Limited, have been incorporated under Ontario charter with a share capital of $40,000, for the purpose of carrying on a paving and contracting business and treating wood. The provisional directors of the company are, C. W. Laker, G. H. Kilmer, W. H. Irving, G. D. Kelley, chief place of business, Toronto.

The Hadley Cement Co. of Canada, have been incorporated under Dominion charter with a capital stock of $50,000 for the purpose of manufacturing and dealing in leather and rubber cement. The provisional directors are W. O. Hadley, D. J. Herlihy, J. P. Dent, W. J. George and Thos. Hall, with head office at Cote St. Paul, Que.

The Automobile Company of Hamilton has been incorporated under Ontario charter with a share capital of $40,000 for the purpose of manufacturing and dealing in motor vehicles and supplies. The provisional directors are: W. R. Moore, H. H. Hodgson, W. M. Clendenning, S. D. Biggar, and John Jackson, with head office at Hamilton.

The Nova Scotia Land Co., Limited, incorporated under Dominion charter with a total capital stock of $200,000 to carry on a real estate and constructing business. The directors of the company are, R. V. Sinclair, A. F. May, A. MacFarlane, W. H. Middleton, and C. T. Moffatt; chief place of business to be Halifax, N.S.

The Windsor Dredging Co., Limited, have been incorporated under provincial charter with a capital stock of $40,000, for the purpose of constructing and maintaining machinery and dredging apparatus and carrying on dredging and dock work. Head office, city of Windsor. The directors being, A. G. Drake, A. Peltier, W. J. McKee, H. W. Allan and G. E. Brooks.

The Contractors' Supply Co. have been incorporated under Ontario charter with a share capital of $100,000 for the purpose of manufacturing and dealing in builders' supplies and structural material. The provisional directors are T. W. Self, Frank Saunders, Richard Chalkley, W. Smallwood, J. Crang, F. R. Love and T. E. Cannon, with head office at Toronto.

The Ionontok Estate Co. incorporated under Dominion charter; total capital stock, $30,000; to purchase and maintain land and to manufacture steam, gas and electricity. Directors of the company are V. E. Mitchell, A. R. Holden, C. H. McLeod, A. A. Robertson, H. M. Jaquays, A. F. Byers, and C. W. Gamble, with chief place of business at Montreal.

The Montreal Reduction and Smelting Co. of Canada has been incorporated under Dominion charter with a capital stock of $2,000,000 for the purpose of carrying on a mining and smelting business. The provisional directors are: J. B. E. Leonard, B. Burland, L. J. Cartier, A. Robert, A. Tremblay, P. Theriault, J. E. Theriault, O. Lemire, P. Tetrault, O. Theriault, J. M. Mitchell, J. H. Brown, O. Frechette, and E. L. Patenaude, with chief place of business at Montreal.

INDUSTRIAL PROGRESS

MACHINERY AND MANUFACTURING NEWS would be pleased to receive from any authoritative source industrial news of any sort, the formation or incorporation of companies, establishment or enlargement of mills, factories or foundries, railway or mining news, etc. All such correspondence will be treated as confidential when desired.

An iron foundry will be built at Red Deer, Alta.

Little Bros.' sawmill was destroyed at Haileybury, Ont.

Calgary permits this year have reached a half million.

N. A. Beach will build a saw mill at Georgeville, Que.

Pembroke, Ont., asks for tenders for a new town hall.

The Hoidge Marble Co. will build a factory in Toronto.

The town of Indian Head is installing a waterworks system.

Carberry, Man., asks for tenders for an electric light plant.

John E. Smith, of Brandon, will erect a block to cost $50,000.

Regina has voted $37,550 for public improvements this year.

The Norton Mfg. Co., Hamilton, will build a $5,000 addition.

Sburly & Dietrich, Galt, Ont., are erecting a new warehouse.

Brantford has issued permits to the amount of $100,765 this year.

Winnipeg has selected a site for a new bridge across the Red River.

Richmond, Que., will spend $25,000 on their waterworks system.

The Victor Beaudry Estate, Montreal, will erect a $30,000 building.

The Alberta Milling Co. will double their capacity at Edmonton.

St. Catharines building permits so far this year amount to $200,000.

The township of Brighton, Ont., will erect three new steel bridges.

The Western Elevator Co. will build a large elevator at Fort William.

R. McQuarrie will build a lumber and shingle mill at Port Kells, B.C.

The Saskatchewan Hotel Co. will erect a $150,000 hotel at Regina, Sask.

G. H. Walton will build an apartment block in Winnipeg to cost $80,000.

The Dow Cereal Co. contemplate building an oatmeal mill at Minnedosa.

J. R. Booth will build an addition to his paper mill at Chaudiere Falls.

The Imperial Oil Co. will erect an oil warehouse at Portage La Prairie.

The Barber Asphalt Co. will establish a permanent works in Vancouver.

The Regina city council will spend $400,000 on street improvements.

The Shipman Electrical Supply Co. has opened showrooms in Winnipeg.

The Calgary Milling Co. have let contracts for a 1,000-barrel flour mill.

Fort William has issued building permits representing $90,000 this year.

The Dominion Iron & Steel Co. shipped during April 15,500 tons of steel.

Winnipeg building permits for 1906 have passed the three million mark.

J. Y. Griffin, of Winnipeg, will build a cold storage plant at Fort William.

L. Higgins & Co., Moncton, N.B., will build a shoe factory at Yarmouth, N.S.

The Berlin Interior Hardwood Co. are building a large addition to their plant.

The Vancouver Warehouses will erect a $70,000 bonded warehouse in that city.

The Canadian Canners will establish a third plant at Hamilton to cost $20,000.

The Nova Scotia Steel Co.'s machine shops at Bell Island were destroyed by fire.

Richmond, Que., has passed a by-law to raise $25,000 for a waterworks system.

Herbert Radford has let the contract for a five-storey warehouse in Winnipeg.

A firm named Compeau & Leduc will put in a saw mill plant at Hazelton, B.C.

The farmers near Tenby, Man., are organizing a company to build a flour mill.

J. Burnside, Hamilton, will open a sash and door factory at Lethbridge, Alta.

John E. Askwith and others have purchased a site for a mica factory in Ottawa.

Carman, Man., ratepayers will vote on a by-law to install an electric light plant.

The Natural History Society, of Montreal, will erect a museum this year.

AN APPRECIATION FROM THE SOUTH

Professor C. M. McKergow, professor of mechanical engineering, University of Virginia, writes, "Let me express my appreciation of your interesting and practical paper. I can say without hesitation that no paper coming into our library is more sought after by our engineering students."

Darling & Pearson ask for tenders for a laboratory for the University of Toronto.

Fred Fry has the contract for installing a waterworks system at Indian Head.

The Kemp Manufacturing Co. ask for tenders for a six-storey factory in Winnipeg.

Cline's furniture factory at Stratford was damaged by fire to the extent of $3,000.

The contract has been let for the building of Crowe's Iron Works plant at Guelph.

B. B. McCarthy, reeve of Thamesford, Ont., asks for tenders for five cement bridges.

Cassette & Trudel's sawmill at St. Tite, Que., was destroyed by fire. Loss $10,000.

Within eight months Fort Frances will have 30,000 horse-power ready for distribution.

Since the fire at Fort Frances, Ont., the amount of buildings started is $230,000.

Port Arthur has already a half million worth of buildings contracted for this year.
